

Study on UAV Launch Strategy of Smoke Interference Grenades

Team Number: _____

December 23, 2025

Abstract

Precision-targeted smoke interference grenades can form a shielding in a specific airspace ahead of the target, effectively interfering with enemy missiles. This paper addresses the issue of unmanned aerial vehicles (UAVs) deploying smoke interference grenades to protect targets, establishing a mathematical model based on kinematics and spatial geometry. By analyzing the relative motion and positional relationship between the missile and the smoke cloud, the optimal deployment strategies under different scenarios are obtained to maximize the effective shielding time.

For **Problem 1**, the flight strategy and bombing strategy of the unmanned aircraft FY1 are known. We have established a model for the movement and diffusion of the smoke grenade. By calculating the spatial position and diffusion radius of the smoke grenade upon explosion, combined with the movement trajectory of the missile M1, we perform **time-step discretization simulation**. Additionally, using **the shielding determination indicator function**, we can determine that the effective shielding duration is 1.4 seconds.

For **Problem 2**, we took the drone's flight direction, speed, drop point, and detonation point as **the decision variables**, and set the shielding time as the objective function to establish a **nonlinear programming model**. To enhance the solution efficiency, we adopted a two-layer optimization strategy to determine the flight parameters and drop strategies that would result in the longest shielding time.

For **Problem 3**, based on Problem 2, multiple smoke grenades were introduced to transform the problem into a **multi-variable optimization problem** with temporal sequence constraints. In view of the tendency of traditional optimization algorithms to get stuck in a stagnant state when dealing with multi-variable situations, we introduced the improved particle swarm algorithm with catastrophe mechanism to find the optimal release timing and detonation plan for multiple smoke interference grenades, and stored the results in the file result1.xlsx.

For **Problem 4**, the task has been changed to have three unmanned aircraft jointly intercept a missile. The core issue lies in **coordinating the bombing strategies** of the three unmanned aircraft, which are in different spatial positions. Therefore, we chose **the robust differential evolution**

algorithm (DE) with strong adaptability to solve the decision variables for multiple unmanned aircraft, obtain the optimal strategy, and store the results in the "result2.xlsx" file.

For **Problem 5**, the model is expanded to include **multiple aircraft and multiple projectiles cooperating to counter multiple missiles**. It also involves the planning of the flight trajectories of unmanned aircraft and the selection of the timing for the deployment of smoke grenades, featuring significant **spatio-temporal coupling characteristics and high-dimensional complexity**. To address this, we continue to use the two-layer optimization model employed in Problem 2, effectively decoupling the trajectory planning and bomb deployment scheduling problems. **The outer layer** employs a **genetic algorithm** to optimize the flight parameters of the unmanned aircraft to determine a reasonable spatial orientation; **the inner layer**, given a flight trajectory, uses a **greedy strategy** to efficiently schedule the timing of the deployment of smoke grenades, maximizing the time of shielding against incoming missiles while satisfying the constraints on the number of ammunition and time intervals. Finally, the optimal collaborative strategy was obtained and saved in the file result3.xlsx.

1 Problem Restatement

1.1 Problem Background

In modern warfare, the use of unmanned aircraft to drop smoke screens and decoy shells is an effective method for protecting important ground targets. It has the advantages of low cost and high cost-effectiveness. After the smoke shells explode in the air, they form a cloud, providing cover and interfering with enemy missiles. This question requires considering the movement trajectories of multiple objects in the given battlefield environment (including the positions of incoming missiles, unmanned aircraft, targets, and physical parameters), and designing the flight and deployment strategies of the unmanned aircraft to achieve the maximum shielding effect.

Figure 1: Problem Background

1.2 Problem Formulation

- **Problem 1** For the specific flight parameters of the given single unmanned aircraft $FY1$, a mathematical model is established based on kinematics, and the effective shielding duration of the missile $M1$ is calculated.
- **Problem 2** Starting from the special case of the first question, it was extended to the general situation. The strategy for a single unmanned aircraft $FY1$ to drop one smoke grenade (including direction, speed, drop point, and detonation point) was optimized to maximize the shielding time.
- **Problem 3** In the case of a single unmanned aircraft $FY1$ releasing multiple smoke grenades, the delivery sequence of the smoke grenades should be planned to maximize the total coverage time.
- **Problem 4** Unlike the situation where there are multiple smoke grenades on a single aircraft, this time it becomes a coordinated operation among multiple aircraft

($FY1 - FY3$), each dropping 1 grenade to counter $M1$, and the optimal strategy for their deployment needs to be found.

- **Problem 5** The all-factor collaborative scenario requires finding the optimal strategy for (5 unmanned aircraft, each carrying a maximum of 3 missiles) to counter 3 missiles ($M1 - M3$).

2 Problem Analysis

2.1 Analysis of Problem 1

The first problem is the simplest scenario, which requires calculating the effective shielding time under the given parameters. First, take the spatial position at the moment of the smoke grenade explosion and the spatial position of the missile as the initial values. Subsequently, considering the diffusion radius and combining with the missile's trajectory, find the intersection point of the two, thereby obtaining the effective shielding duration.

2.2 Analysis of Problem 2

Problem 2 is an extension of Problem 1. It requires optimizing the flight direction, speed, drop point, and detonation point of the unmanned aircraft as decision variables, with the goal of maximizing the shielding time as the objective function, to obtain the optimal solution under certain constraints. Achieve the best deployment strategy for smoke grenades.

2.3 Analysis of Problem 3

Problem 3 is an optimization of Problem 2. It requires controlling the timing of the deployment of smoke grenades, coordinating the simultaneous deployment of smoke grenades, to achieve a multi-grenade relay shielding effect, thereby maximizing the effective shielding time.

2.4 Analysis of Problem 4

Problem 4 pertains to the scenario of multi-vehicle collaboration. It requires considering the coordination of multiple unmanned aircraft in terms of time and space, aiming to maximize the shielding effect in both spatial and temporal dimensions.

2.5 Analysis of Problem 5

Problem 5 is the most complex scenario, involving multiple vehicles and multiple grenades countering multiple missiles. It requires comprehensive consideration of UAV task allocation, trajectory planning, and smoke grenade deployment timing, among other factors, to establish a comprehensive optimization model to maximize overall shielding effectiveness. However, directly considering all decision variables results in high time and space complexity, making direct solution infeasible. Therefore, the problem needs to be simplified and transformed into a multi-agent collaborative task allocation and deployment strategy problem.

2.6 Overall Analysis

Based on the above requirements, we have carried out the work shown in Figure 2:

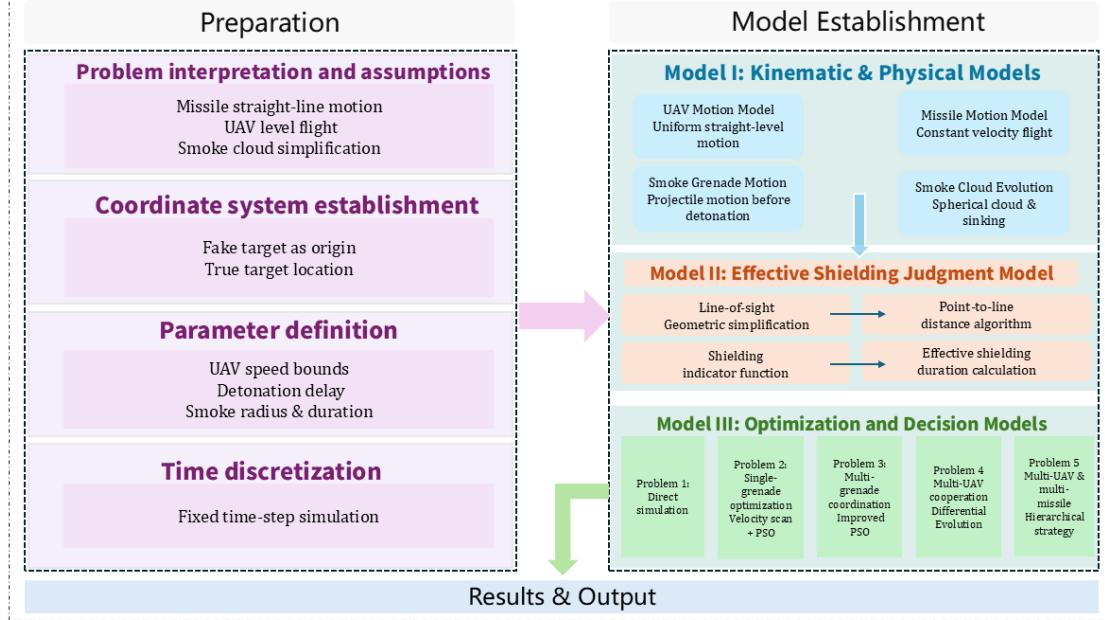

Figure 2: Overall Analysis Framework

3 Model Assumptions

To simplify the problem, the main assumptions are as follows:

1. The smoke grenade undergoes simple projectile motion under gravity after release, ignoring air resistance.
2. The smoke cloud forms a perfect sphere and maintains a stable radius (or diffuses/sinks at a constant rate as specified).
3. The incoming missle travels in a uniform straight line without maneuvering.
4. The radar detection time is set as $t = 0$.
5. The turning radius of the drone is ignored; direction changes are considered instantaneous.
6. The drone, missle, smoke grenade, and smoke cloud are all considered as point masses.

4 Notation

The main symbols used in this paper are defined in Table 1:

Table 1: Notation

| Symbol | Definition | Unit |
|---------------------------|---|------------------|
| M_j | The j -th incoming missile ($j = 1, 2, 3$) | - |
| FY_i | The i -th drone ($i = 1, 2, 3, 4, 5$) | - |
| V_m | Missile velocity (Fixed at 300) | m/s |
| v_{FY_i} | The i -th drone flight velocity | m/s |
| \mathbf{v}_{FY_i} | The i -th drone velocity vector | m/s |
| \mathbf{n}_{M_j} | The j -th missile flight direction unit vector | - |
| $\alpha (\alpha_i)$ | The heading angle of the i -th drone | rad |
| g | Gravitational acceleration (9.8) | m/s ² |
| \mathbf{P}_O | Decoy target position (0, 0, 0) | m |
| \mathbf{P}_T | True target position (0, 200, 5) | m |
| $\mathbf{P}_{M_j}(t)$ | Position of the j -th missile at time t | m |
| $\mathbf{P}_{FY_i}(t)$ | Position of the i -th drone at time t | m |
| $\mathbf{P}_{drop,k}$ | Position of the k -th smoke grenade release | m |
| $\mathbf{P}_{burst,k}$ | Position of the k -th smoke grenade detonation | m |
| $\mathbf{P}_{S,k}(t)$ | Position of the k -th smoke cloud at time t | m |
| t | Current time | s |
| $t_{drop} (t_{drop,k})$ | (The k -th) smoke grenade release time | s |
| $t_{burst} (t_{burst,k})$ | (The k -th) smoke grenade detonation time | s |
| $t_{delay} (t_{delay,k})$ | (The k -th) smoke grenade detonation delay | s |
| Δt | Discretized time step | s |
| T_{end} | End time | s |
| T_{cover} | Total effective screening time | s |
| R_{cloud} | Effective screening radius of smoke cloud (Fixed at 10) | m |
| v_{cloud} | Descent velocity of smoke cloud (Fixed at 3) | m/s |
| $D(t) (D_{k,j}(t))$ | Distance from the center of the k -th smoke cloud to the line connecting the j -th missile and the target | m |
| $I_j(t)$ | Screening indicator function for the j -th missile | - |
| $I_{i,k,j}(t)$ | Screening indicator function of the i -th drone's k -th grenade for the j -th missile | - |
| $I_{total}(t)$ | Total system screening status (logical OR) | - |
| $S_j(t)$ | Screening status of the j -th missile in the entire system | - |
| $X (\mathbf{X})$ | Decision variable vector | - |
| $J(X)$ | Objective function (screening time) | s |
| F | Differential evolution scaling factor | - |
| λ | Penalty function weight coefficient | - |
| $N (NP)$ | Population size/number of particles | - |
| G_{max} | Maximum number of iterations | - |

5 Model establishment

The incoming missiles always use the actual target as the guidance object during their flight. The detection and guidance process can be roughly understood as obtaining information along the line of sight from the missile's current position to the target. The smoke screen decoy released by the unmanned aircraft forms a high-concentration smoke cloud

upon detonation, blocking the direct detection line of the missile to the target, thereby reducing the missile's ability to identify and lock onto the target. Therefore, the essence of the smoke screen interference effect does not depend on whether the smoke cloud "contacts" the missile or the target itself, but on whether the smoke cloud covers the key line of sight between the missile and the target in space. Based on this understanding, this paper abstracts the core of the smoke screen interference problem as a **time-varying spatial geometric shielding determination problem**, and further quantifies the effective shielding time on this basis. According to the description of the problem, a unified three-dimensional Cartesian coordinate system $Oxyz$ is first established. Taking the center of the false target as the origin, the x and y axes are located on the horizontal plane, and the z axis is vertically upward. Then, the position of the false target is $P_O = (0, 0, 0)$, and the true target is at point $P_T = (0, 200, h_T)$, where $h_T = 5m$ is the height of the center of the true target.

5.1 Missile Motion Model Construction

According to the description of the problem, the incoming missiles always lock onto the false target as their attack object. The initial positions of missiles M1-M3 are given, and their flight speed is fixed at $V_m = 300 \text{ m/s}$, while the false target is located at the coordinate origin $(0, 0, 0)$. Since the motion patterns of missiles M1, M2, and M3 are the same in problems one to five, only their initial positions differ. Therefore, to uniformly describe the motion characteristics of multiple missiles, a general missile motion mathematical model needs to be established. First, we consider the initial position of the j -th missile as point $P_{M_j}(0)$, then the initial direction vector of the missile is:

$$\mathbf{n}_{M_j} = \frac{\mathbf{P}_O - \mathbf{P}_{M_j}(0)}{\|\mathbf{P}_O - \mathbf{P}_{M_j}(0)\|} \quad (1)$$

Since the missile moves at a constant speed V_m in a straight line, we can determine its position at any time t :

$$\mathbf{P}_{M_j}(t) = \mathbf{P}_{M_j}(0) + V_m \cdot t \cdot \mathbf{n}_{M_j} \quad (2)$$

5.2 Construction of unmanned aerial vehicle motion model

According to the description of the problem, the initial positions of unmanned aerial vehicles FY1-FY5 are given as FY1(17800,0,1800), FY2(12000,1400,1400), FY3(6000,-3000,700), FY4(11000,2000,1800), and FY5(13000,-2000,1300). Their flight speed ranges from [70, 140] m/s, and they maintain constant altitude and uniform linear motion.

In problem one, the UAV speed is 120 m/s, flying towards the false target; In problems two to five, the flight speed v_{FY_i} and heading angle α_i are decision variables to be optimized. The problem emphasizes that "once the UAV receives the mission, its speed and heading are determined and will not be adjusted", which means the UAV maintains uniform speed and constant altitude linear flight throughout the mission. Therefore, we can represent the initial position of the i -th UAV as $\mathbf{P}_{FY_i}(0)$, and its flight parameters as flight speed v_{FY_i} and heading angle α_i , thus we can obtain its velocity vector, expressed as:

$$\mathbf{v}_{FY_i} = v_{FY_i} (\cos \alpha_i, \sin \alpha_i, 0) \quad (3)$$

From this, we can determine the position of the UAV at any time t :

$$\mathbf{P}_{FY_i}(t) = \mathbf{P}_{FY_i}(0) + \mathbf{v}_{FY_i}t \quad (4)$$

5.3 Construction of smoke screen interference bomb motion model

According to the description of the problem, the smoke screen interference bomb has the following characteristics:

Drop Delay t_{drop} : How long after the drone receives the mission will it drop the smoke grenade

Explosion Delay $t_{delay} \in [1, 8]$ s: How long after the smoke grenade is dropped will it explode

Smoke Radius $R_{cloud} = 10$ m: The effective shielding radius of the smoke cloud formed after explosion

Sinking Speed $v_{cloud} = 3$ m/s: The uniform sinking speed of the smoke cloud

Effective Time: The smoke cloud maintains its effective shielding capability for 20 seconds after the explosion. The motion of the smoke screen interference bomb can also be divided into two parts: the delivery phase (from delivery to explosion) and the explosion phase (after explosion). Then, the k -th smoke screen interference bomb is delivered at $t_{drop,k}$, after a delay of $t_{delay,k}$, and under the acceleration of gravity g , its motion can be decomposed into free fall motion in the vertical direction and uniform linear motion in the horizontal direction, as shown in Figure 3, and the explosion time can be obtained as:

$$t_{burst,k} = t_{drop,k} + t_{delay,k} \quad (5)$$

The explosion position is

$$\mathbf{P}_{burst,k} = \mathbf{P}_{FY_i}(t_{drop,k}) + \mathbf{v}_{FY_i}t_{delay,k} - \left(0, 0, \frac{1}{2}gt_{delay,k}^2\right) \quad (6)$$

After the smoke screen bomb explodes, it forms a spherical cloud with radius R_{cloud} , whose center sinks uniformly at a constant speed v_{cloud} . Therefore, we can obtain the position of the smoke screen bomb at any time after the explosion as:

$$\mathbf{P}_{S,k}(t) = \mathbf{P}_{burst,k} - (0, 0, v_{cloud}(t - t_{burst,k})), \quad t \geq t_{burst,k} \quad (7)$$

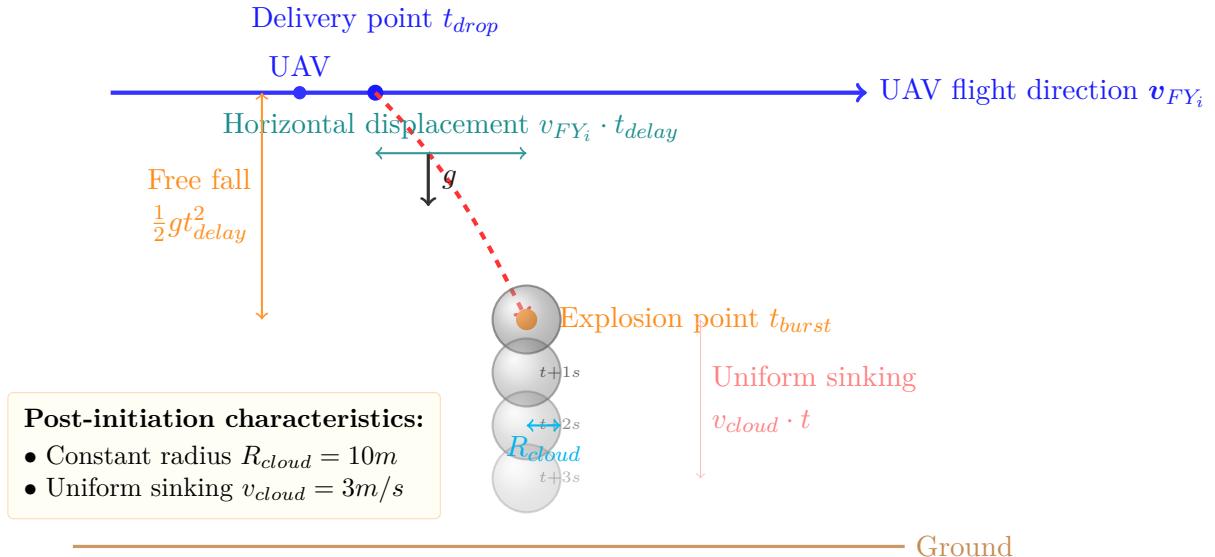

Figure 3: Smoke grenade trajectory and cloud sinking illustration

5.4 Effective Obstruction Determination Model

5.4.1 Geometric Obstruction Conditions

Problem Background and Simplifying Assumptions According to the initial conditions given in the problem, three missiles M1, M2, and M3 are located at (20000,0,2000), (19000,600,2100), and (18000,−600,1900), UAV FY1 is located at (17800,0,1800), FY2 at (12000,1400,1400), FY3 at (6000,−3000,700), FY4 at (11000,2000,1800), FY5 at (13000,−2000,1300), and the true target (a cylinder with base center at (0, 200, 0), base radius 7 m, and height 10 m) is tens of thousands of meters away from both. At such a long distance, the geometric size of the target (radius 7 m) is negligible compared to the line of sight length (about 20 km). Based on the following reasonable assumptions, this paper simplifies the obstruction determination model.

1. **Target Point Simplification:** The true target is simplified to its centroid point $P_T = (0, 200, 5)$ (base center plus half height 5 m), ignoring its geometric size. This simplification is reasonable for long-distance optical/infrared detection and aligns with the small-angle approximation in geometric optics.
2. **Missile Field of View Assumption:** The problem does not explicitly limit the missile's field of view. Considering the characteristics of practical inertial-guided missiles, it can be assumed that the missile detector's field of view is sufficiently large to cover a reasonable area in the target direction. Therefore, only obstruction in the line of sight direction needs to be considered, without considering the field of view boundaries.
3. **Line of Sight Segmentation:** The optical detection path of the missile can be abstracted as the line segment AB connecting the missile position A and the target position B . When the spatial distance between the smoke cloud center and this line segment is less than the smoke radius, the line of sight is effectively obstructed.

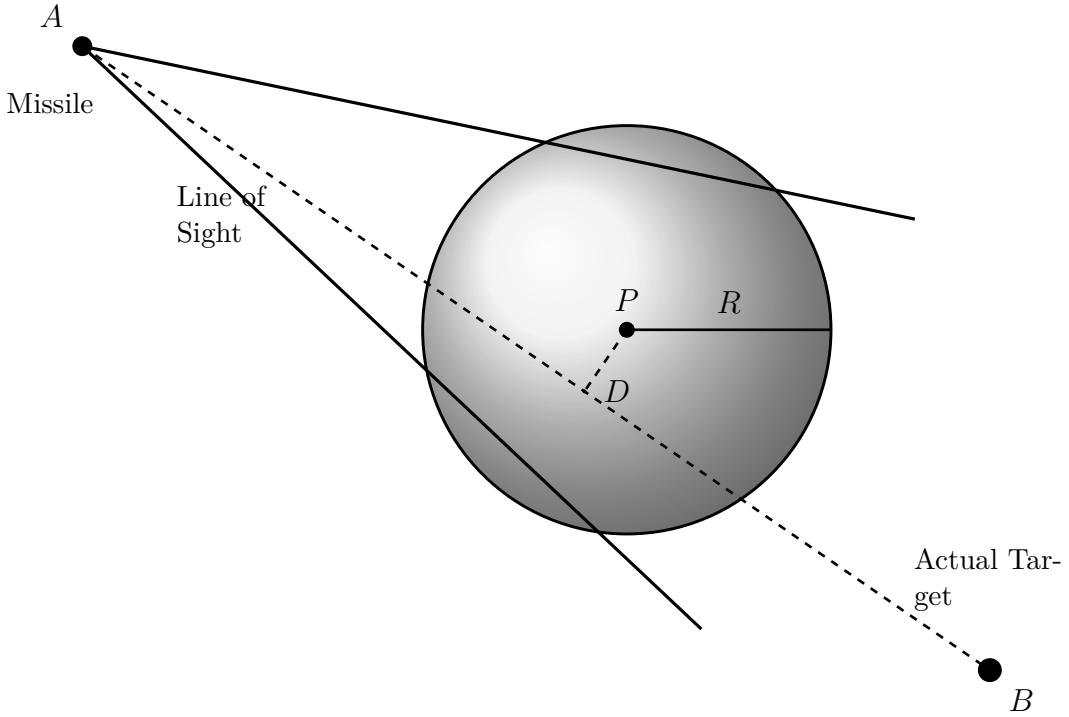

Based on the above simplifications, the simplified obstruction schematic relationship is shown in Figure 4, where the missile line of sight is obstructed if $D \leq R$. The necessary

and sufficient condition for effective obstruction can be expressed as:

$$D(t) \leq R_{cloud} \quad (8)$$

where $D(t)$ is the **shortest distance** (point-to-line segment distance) from the smoke cloud center $\mathbf{P}_S(t)$ at time t to the line segment $P_M(t)P_T$ representing the line of sight vector, $R_{cloud} = 10\text{ m}$ is the effective obstruction radius of the smoke cloud. Therefore, solving for $D(t)$ is particularly important. Next, we will introduce the method for calculating the distance from a point to a line segment.

Figure 4: Missile-Smoke Grenade-Target Obstruction Model Schematic

5.4.2 Point-to-Segment Distance Algorithm

Let the missile position be point A, the actual target position be point B, and the smoke grenade center be point P. The vector $\vec{AB} = B - A$, and the vector $\vec{AP} = P - A$. The projection coefficient r is calculated as:

$$r = \frac{\vec{AP} \cdot \vec{AB}}{\|\vec{AB}\|^2} \quad (9)$$

The distance is discussed in three cases, as shown in Figure 5:

$$D(t) = \begin{cases} \|\vec{AP}\| & \text{if } r \leq 0 \text{ (behind the missile)} \\ \|\vec{P} - \vec{B}\| & \text{if } r \geq 1 \text{ (behind the target)} \\ \frac{\|\vec{AP} \times \vec{AB}\|}{\|\vec{AB}\|} & \text{if } 0 < r < 1 \text{ (projection within the segment)} \end{cases} \quad (10)$$

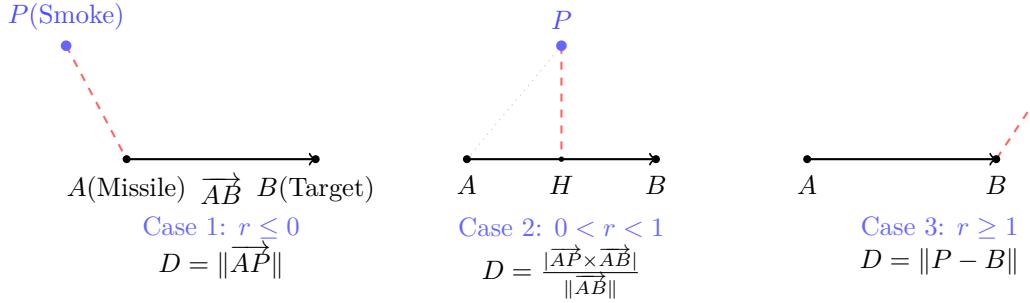

Figure 5: Three cases of point-to-segment distance calculation

5.5 Shading Time Model

5.5.1 Shading Indicator Function

To quantitatively describe the shielding effect of the smoke cloud layer on missiles, the **shielding indicator function** $I_j(t)$ is introduced, which is used to represent whether the j -th missile is effectively shielded at time t . The function is defined as:

$$I_j(t) = \begin{cases} 1, & \text{if } D_{k,j}(t) \leq R_{cloud} \text{ and } t \geq t_{burst,k} \\ 0, & \text{otherwise} \end{cases} \quad (11)$$

Here, $D_{k,j}(t)$ represents the point-to-line segment distance between the k th smoke grenade and the j th missile at time t . $R_{cloud} = 10$ m: the effective shielding radius of the smoke cloud. $t_{burst,k}$ is the detonation time of the k th smoke grenade. This indicator function has the following physical meaning:

1. When $t < t_{burst,k}$, the smoke grenade has not yet detonated, so $I_j(t) = 0$ (no shielding).
2. When $t \geq t_{burst,k}$ and $D_{k,j}(t) \leq R_{cloud}$, the smoke cloud effectively blocks the line of sight, so $I_j(t) = 1$ (effective shielding).
3. When $D_{k,j}(t) > R_{cloud}$, the smoke cloud is too far from the line of sight, so $I_j(t) = 0$ (shielding ineffective).

5.5.2 Total Effective Shading Duration

For a single missile j , the total effective shading duration during the entire flight process $[0, T_{end}]$ is defined as the time integral of the indicator function.

$$T_j = \int_0^{T_{end}} I_j(t) dt \quad (12)$$

Here, T_{end} is the missile flight termination time. Through this integral, we can calculate the cumulative time during which the missile is effectively shaded by the smoke cloud throughout its flight. In scenarios involving multiple missiles (M_1, M_2, \dots, M_m) cooperating in interception, the overall system optimization objective is defined as the sum of the shading durations of all missiles:

$$\max T_{cover} = \sum_{j=1}^m T_j \quad (13)$$

This objective function reflects the tactical requirement of "maximizing overall protection effectiveness."

5.5.3 Time Discretization Strategy

Due to the continuous time-varying motion of multiple entities such as missiles and smoke clouds in the system, and the shielding determination conditions involving complex geometric relationships and nonlinear logic, it is not possible to directly solve the shading time integral $\int_0^{T_{end}} I_j(t) dt$ analytically. Therefore, this paper adopts a time discretization method, as shown in Figure 6, dividing the continuous time axis into equally spaced discrete time points:

$$t_k = k\Delta t, \quad k = 0, 1, 2, \dots, N \quad (14)$$

where Δt is the time step size, and $N = \lfloor T_{end}/\Delta t \rfloor$. At each discrete time point t_k , first, based on the kinematic equations, update the missile position $\mathbf{P}_{M_j}(t_k)$ and the center position of the smoke cloud $\mathbf{P}_{S,k}(t_k)$. Then, calculate the distance from the point to the line segment $D_{k,j}(t_k)$. Next, according to the shielding determination conditions, determine the shielding state $I_j(t_k) \in \{0, 1\}$. Finally, the effective shielding duration can be approximated by the **Riemann sum**:

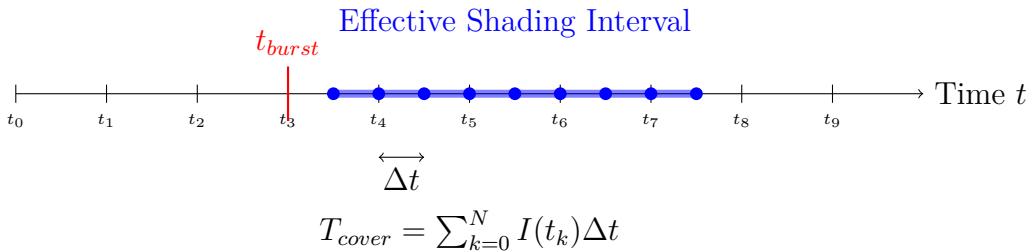

$$T_{cover} \approx \sum_{k=0}^N I(t_k) \cdot \Delta t \quad (15)$$

This formula essentially represents the numerical calculation of a definite integral. As $\Delta t \rightarrow 0$, the discrete sum converges to the exact value of the continuous integral. The choice of time step size must balance computational accuracy and efficiency:

- **Coarse scanning phase** (initial search): $\Delta t = 0.1s$, quickly locating potential shading intervals
- **Fine calculation phase** (optimization solving): $\Delta t = 0.01s$ or $0.001s$, ensuring accuracy

This method is not only suitable for single-target single-missile scenarios, but also efficiently handles overlapping time windows and shading unions in multi-UAV multi-missile cooperative problems.

Figure 6: Time Discretization and Accumulation of Shading Duration

6 Model Solution

6.1 Problem 1 Solution: Fixed Parameters

Problem 1 focuses on a specific scenario where all parameters (smoke grenade deployment time, detonation time) are given, and the goal is to calculate the effective shading time of a single smoke grenade against a single missile. We need to use the position functions of each object combined with the effective shading criteria to obtain the effective shading time. The problem provides the flight strategy of UAV FY1 (speed, heading) and the bomb deployment strategy (deployment time, detonation delay). The core task of this question is **simulation verification** of the effectiveness of the known strategy. Unlike the subsequent optimization problems (Problems 2 to 5), Problem 1 does not require searching for the optimal solution, but is based on deterministic inputs for numerical simulation. Therefore, a **time discretization simulation method** can be directly used to solve it.

Overview of Solution Steps

1. **Parameter Substitution:** Substitute all given physical parameters into the kinematic equations
2. **Trajectory Calculation:** Calculate the detonation position of the smoke grenade and the time-varying positions of all entities
3. **Shading Determination:** Check at each time step whether the smoke cloud effectively shades the missile's line of sight
4. **Duration Statistics:** Accumulate the time intervals that meet the shading conditions to obtain the total shading duration

6.1.1 Parameter Substitution and Scenario Setup

According to the problem conditions, the initial parameters of each entity are as follows:

UAV FY1 Parameters

- Initial Position: $\mathbf{P}_{FY_1}(0) = (17800, 0, 1800)$ m
- Flight Speed: $v_{FY_1} = 120$ m/s
- Flight Heading: Directed towards the false target $\mathbf{P}_O = (0, 0, 0)$, i.e., velocity vector $\mathbf{v}_{FY_1} = (-120, 0, 0)$ m/s

Missile M1 Parameters

- Initial Position: $\mathbf{P}_{M_1}(0) = (20000, 0, 2000)$ m
- Flight Speed: $V_m = 300$ m/s (directed towards the false target)
- Flight Direction: Unit vector $\mathbf{n}_{M_1} = \frac{\mathbf{P}_O - \mathbf{P}_{M_1}(0)}{\|\mathbf{P}_O - \mathbf{P}_{M_1}(0)\|}$

Smoke Grenade Deployment Strategy

- Deployment Time: $t_{drop} = 1.5 \text{ s}$ (deployed 1.5 seconds after receiving the task)
- Detonation Delay: $t_{delay} = 3.6 \text{ s}$ (detonates 3.6 seconds after deployment)
- Detonation Time: $t_{burst} = t_{drop} + t_{delay} = 5.1 \text{ s}$

Smoke Cloud Physical Parameters

- Effective Radius: $R_{cloud} = 10 \text{ m}$
- Sinking Speed: $v_{cloud} = 3 \text{ m/s}$
- Effective Duration: Maintains shading capability for 20 seconds after detonation

6.1.2 Trajectory Calculation

Based on the motion models established earlier, the spatial positions of all entities in the system vary with time. The UAV's position at the deployment time is $\mathbf{P}_{FY_1} = \mathbf{P}_{FY_1}(t_{drop})$. The detonation time of the smoke grenade is

$$t_{burst} = t_{drop} + t_{delay}, \quad (16)$$

then its detonation position is

$$\mathbf{P}_{burst} = \mathbf{P}_{FY_1}(t_{drop}) + \mathbf{v}_{FY_1} t_{delay} - (0, 0, \frac{1}{2}gt_{delay}^2). \quad (17)$$

After detonation, the center of the smoke cloud sinks vertically at a constant speed. Its position at any time t is

$$\mathbf{P}_S(t) = \mathbf{P}_{burst} - (0, 0, v_{cloud}(t - t_{burst})), \quad t \geq t_{burst}. \quad (18)$$

The position of missile M1 at any time t is

$$\mathbf{P}_M(t) = \mathbf{P}_M(0) + V_M \mathbf{n}_M t, \quad (19)$$

where \mathbf{n}_M is the unit direction vector of the missile pointing towards the false target.

6.1.3 Effective Shading Duration Calculation

To calculate the effective shading duration, the time interval $[0, T_{end}]$ is discretized. The time step is taken as $\Delta t = 0.05 \text{ s}$, and the end time T_{end} is the time when the missile reaches the false target. Discrete time points are defined as:

$$t_k = k\Delta t, \quad k = 0, 1, \dots, N, \quad N = \lfloor T_{end}/\Delta t \rfloor \quad (20)$$

Step-by-Step Shading Determination At each discrete time t_k , the following determination process is executed:

1. **Time Window Check:** If $t_k < t_{burst}$ or $t_k > t_{burst} + 20$, the smoke grenade has not detonated or has expired, so $I(t_k) = 0$
2. **Spatial Position Update:** Calculate $\mathbf{P}_{M_1}(t_k)$, $\mathbf{P}_S(t_k)$, and the true target position $\mathbf{P}_T = (0, 200, 5)$
3. **Distance Calculation:** Calculate the shortest distance $D(t_k)$ from the center of the smoke cloud to the line connecting the "missile-target" (point-to-line segment distance algorithm)
4. **Obstruction Detection:** If $D(t_k) \leq R_{cloud} = 10$ m, then $I(t_k) = 1$; otherwise, $I(t_k) = 0$

The shielding indicator function is defined as:

$$I(t_k) = \begin{cases} 1, & D(t_k) \leq R_{cloud} \text{ and } t_k \in [t_{burst}, t_{burst} + 20], \\ 0, & \text{otherwise.} \end{cases} \quad (21)$$

Total Duration Statistics By summing all time points that satisfy the shading condition, the total effective shading duration is obtained:

$$T_{cover} = \sum_{k=0}^N I(t_k) \cdot \Delta t \quad (22)$$

6.1.4 Model Summary

Comprehensive analysis above, the solution model for Problem 1 can be summarized as:

$$\left\{ \begin{array}{l} \textbf{Input Parameters : } \mathbf{P}_{FY_1}(0), v_{FY_1}, t_{drop}, t_{delay}, \mathbf{P}_{M_1}(0), V_m \\ \textbf{Missile Motion : } \mathbf{P}_{M_1}(t) = \mathbf{P}_{M_1}(0) + V_m \mathbf{n}_{M_1} \cdot t \\ \textbf{Drone Motion : } \mathbf{P}_{FY_1}(t) = \mathbf{P}_{FY_1}(0) + \mathbf{v}_{FY_1} \cdot t \\ \textbf{Burst Position : } \mathbf{P}_{burst} = \mathbf{P}_{FY_1}(t_{drop}) + \mathbf{v}_{FY_1} \cdot t_{delay} - (0, 0, \frac{1}{2} g t_{delay}^2) \\ \textbf{Cloud Motion : } \mathbf{P}_S(t) = \mathbf{P}_{burst} - (0, 0, v_{cloud}(t - t_{burst})), \quad t \geq t_{burst} \\ \\ \textbf{Distance Calculation : } D(t) = \begin{cases} \|\mathbf{P}_S(t) - \mathbf{P}_{M_1}(t)\| & \text{if } r \leq 0 \\ \|\mathbf{P}_T - \mathbf{P}_S(t)\| & \text{if } r \geq 1 \\ \frac{\|(\mathbf{P}_S(t) - \mathbf{P}_{M_1}(t)) \times (\mathbf{P}_T - \mathbf{P}_{M_1}(t))\|}{\|\mathbf{P}_T - \mathbf{P}_{M_1}(t)\|} & \text{if } 0 < r < 1 \end{cases} \\ \\ \textbf{Obstruction Detection : } I(t) = \begin{cases} 1, & D(t) \leq R_{cloud} \text{ and } t_{burst} \leq t \leq t_{burst} + 20 \\ 0, & \text{otherwise} \end{cases} \\ \\ \textbf{Output : } T_{cover} = \int_0^{T_{end}} I(t) dt \approx \sum_{k=0}^N I(t_k) \cdot \Delta t \end{array} \right. \quad (23)$$

where the projection coefficient is defined as $r = \frac{(\mathbf{P}_S(t) - \mathbf{P}_{M_1}(t)) \cdot (\mathbf{P}_T - \mathbf{P}_{M_1}(t))}{\|\mathbf{P}_T - \mathbf{P}_{M_1}(t)\|^2}$.

6.1.5 Solution Results:

After calculation, the results are shown in Figure 7, clearly demonstrating the effective duration of the smoke cloud. The smoke grenade burst time is $t = 5.10\text{s}$, the initial burst coordinates are $(17188.00, 0.00, 1736.50)$, the effective shading duration is $8.1 - 9.5\text{s}$, with a total duration of 1.4s .

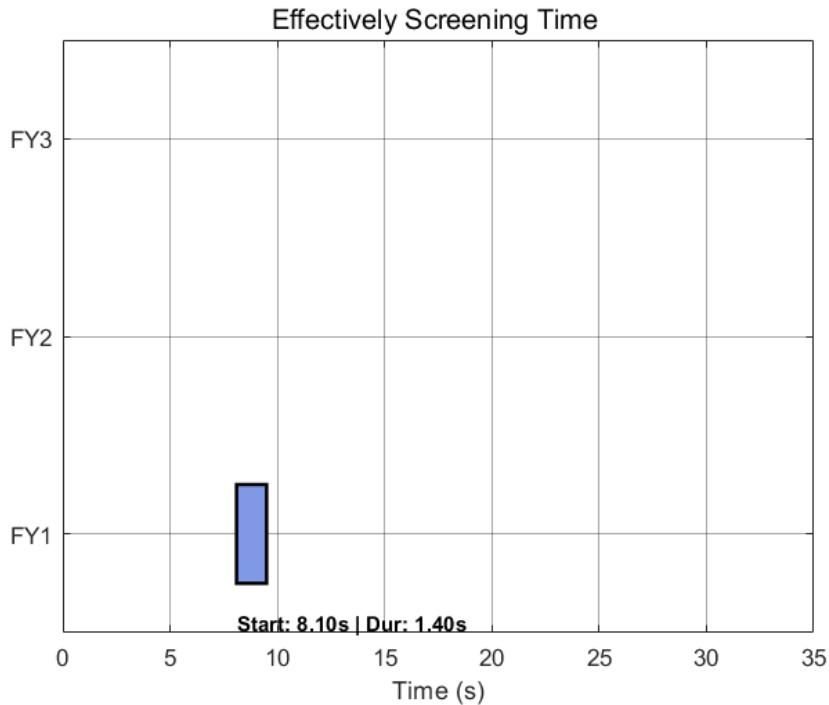

Figure 7: Problem 1 Results

6.2 Problem 2 Solution: Single Drone Single Grenade Optimization

Problem 2 is a generalization and extension of Problem 1. Unlike Problem 1, which involves simulation verification with given parameters, Problem 2 requires optimizing the flight strategy and grenade dropping strategy of drone FY1 under **adjustable parameters** to maximize the effective shading time of a single smoke grenade against missile M1. The core challenge of this problem is that the number of decision variables increases from 0 (all given in Problem 1) to 4, and the objective function $T_{cover}(X)$ is highly nonlinear and non-convex, making it impossible to solve analytically. Therefore, a **nonlinear programming model** needs to be established, and intelligent optimization algorithms should be used for numerical solutions.

6.2.1 Decision Variables

According to the problem requirements, once the drone receives the task, its speed and heading are determined and no longer adjusted. Therefore, when making task decisions, we need to decide the following four variables: As shown in Table 2

Table 2: Description of Decision Variables for Problem 2

| Variable | Physical Meaning | Range |
|-------------|---|------------------|
| v_{FY_1} | Drone flight speed | [70, 140] m/s |
| α | Drone heading angle (relative to x -axis) | [0, 2π] rad |
| t_{drop} | Smoke grenade drop time | [0, 12] s |
| t_{delay} | Smoke grenade burst delay | [1, 8] s |

Define the decision vector as:

$$X = [v_{FY_1}, \alpha, t_{drop}, t_{delay}]^T \in \mathbb{R}^4 \quad (24)$$

These four variables are not independent but are coupled through physical constraints:

- **Speed-Heading Coupling:** v_{FY_1} and α jointly determine the drone's flight trajectory, which in turn affects the smoke grenade drop position \mathbf{P}_{drop}
- **Time-Space Coupling:** t_{drop} determines the drop position, and t_{delay} determines the burst position, both of which jointly affect the relative position between the smoke cloud and the missile's line of sight
- **Altitude Constraint Coupling:** A large t_{delay} may cause the smoke grenade to burst after hitting the ground (violating physical constraints), so the feasible domain of t_{delay} is indirectly constrained by v_{FY_1} , α , and t_{drop}

6.2.2 State Equations

Based on the kinematic model established in Problem 1, the decision variables X are parameterized and embedded into the state equations

Convert scalar speed v_{FY_1} and heading angle α into a three-dimensional velocity vector:

$$\mathbf{v}_{FY_1}(v_{FY_1}, \alpha) = [v_{FY_1} \cos \alpha, v_{FY_1} \sin \alpha, 0]^T \quad (25)$$

Drop point position (dependent on v_{FY_1} , α , t_{drop})

$$\mathbf{P}_{drop}(X) = \mathbf{P}_{FY_1}(0) + \mathbf{v}_{FY_1}(v_{FY_1}, \alpha) \cdot t_{drop} \quad (26)$$

Burst point position (dependent on all four decision variables):

$$\mathbf{P}_{burst}(X) = \mathbf{P}_{drop}(X) + \mathbf{v}_{FY_1}(v_{FY_1}, \alpha) \cdot t_{delay} + [0, 0, -\frac{1}{2}gt_{delay}^2]^T \quad (27)$$

Smoke cloud center trajectory ($t \geq t_{burst}$):

$$\mathbf{P}_S(t; X) = \mathbf{P}_{burst}(X) - [0, 0, v_{cloud}(t - t_{burst})]^T \quad (28)$$

6.2.3 Objective Function

The objective is to maximize the effective coverage duration, using the coverage indicator function defined in Problem 1 to derive the objective function:

$$\max J(X) = T_{cover} = \int_0^{T_{end}} I(t; X) dt \quad (29)$$

Among them, the masking indicator function depends on the decision variable X :

$$I(t; X) = \begin{cases} 1, & D(t; X) \leq R_{cloud} \text{ and } t \geq t_{burst}(X) \\ 0, & \text{otherwise} \end{cases} \quad (30)$$

$D(t; X)$ is the distance from the smoke cloud center $\mathbf{P}_S(t; X)$ to the missile's line of sight (point-to-line segment distance).

6.2.4 Constraints

Based on the problem requirements and analysis of the model's velocity characteristics, the constraints are as follows:

Speed constraint: After receiving the mission, the drone instantaneously adjusts its flight direction, then flies at a constant altitude with a uniform linear speed between 70 and 140 m/s

$$70 \leq v_{FY_1} \leq 140 \quad (31)$$

Time constraint: The upper limit of the drop time is 12 seconds considering the missile's flight speed; dropping too late may miss the interception opportunity.

$$0 \leq t_{drop} \leq 12, 1 \leq t_{delay} \leq 8 \quad (32)$$

Altitude constraint: The smoke grenade must burst in the air, so the burst point's altitude must be greater than zero

$$z_{burst}(X) > 0 \quad (33)$$

6.2.5 Model Summary

Based on the above analysis, the complete optimization model for Problem 2 can be expressed as:

$$\left\{ \begin{array}{l} \text{Decision variables: } X = [v_{FY_1}, \alpha, t_{drop}, t_{delay}]^T \\ \text{Objective function: } \max T_{cover}(X) = \int_0^{T_{end}} I(t; X) dt \\ \text{State equations: } \begin{cases} \mathbf{v}_{FY_1} = v_{FY_1} [\cos \alpha, \sin \alpha, 0]^T \\ \mathbf{P}_{drop} = \mathbf{P}_{FY_1}(0) + \mathbf{v}_{FY_1} \cdot t_{drop} \\ \mathbf{P}_{burst} = \mathbf{P}_{drop} + \mathbf{v}_{FY_1} \cdot t_{delay} + [0, 0, -\frac{1}{2}gt_{delay}^2]^T \\ \mathbf{P}_S(t) = \mathbf{P}_{burst} - [0, 0, v_{cloud}(t - t_{burst})]^T \end{cases} \\ \text{Coverage determination: } I(t; X) = \begin{cases} 1, & D(t) \leq R_{cloud} \text{ and } t_{burst} \leq t \leq t_{burst} + 20 \\ 0, & \text{otherwise} \end{cases} \\ \text{Constraints: } \begin{cases} 70 \leq v_{FY_1} \leq 140 \\ 0 \leq t_{drop} \leq 12, \quad 1 \leq t_{delay} \leq 8 \\ z_{burst}(X) > 0 \end{cases} \end{array} \right. \quad (34)$$

6.2.6 Solution Algorithm

Due to the complex geometric motion and piecewise logic involved in the objective function, it exhibits high nonlinearity and non-convexity, and the decision variables have higher degrees of freedom compared to typical single-variable optimization problems. Therefore, to solve such problems, this problem adopts a two-level optimization strategy, with grid search in the outer loop and particle swarm optimization (PSO) in the inner loop. This reduces the optimization problem dimension from 4 to 3, lowering the search difficulty and reducing the probability of the problem falling into local optima.

Outer loop:

We use the **grid search method**, first discretizing the speed v_{FY_1} in the interval $[70, 140]$ with a step size of $\Delta v = 0.5 \text{ m/s}$

$$v_{FY_1} \in \{70.0, 70.5, 71.0, \dots, 139.5, 140.0\} \quad (35)$$

Then, for each discrete speed value, the inner PSO algorithm is called to solve the subproblem

$$\max_{(\alpha, t_{drop}, t_{delay})} T_{cover}(v_{FY_1}, \alpha, t_{drop}, t_{delay}) \quad (36)$$

Record the optimal solution $(\alpha^*, t_{drop}^*, t_{delay}^*)$ and its objective function value corresponding to each v_{FY_1} , and finally select the global optimum.

Inner loop:

We use the particle swarm optimization algorithm (PSO). First, we perform **particle encoding**, representing the position of the i -th particle as $x_i = [\alpha_i, t_{drop,i}, t_{delay,i}]$, and its velocity as v_i ; thus, each particle represents a candidate solution x_i . Then we proceed with **parameter setting**, setting the population size to N to 30, the maximum number of iterations G_{max} to 50 times, the inertia weight w to 0.6 to balance global and local search, and the learning factors $c_1 = c_2$ to 1.5 to balance individual cognition and social learning. Meanwhile, the **velocity and position update formulas for particles** are

$$v_i^{k+1} = w \cdot v_i^k + c_1 r_1 \odot (p_{best,i} - x_i^k) + c_2 r_2 \odot (g_{best} - x_i^k) \quad (37)$$

$$x_i^{k+1} = x_i^k + v_i^{k+1} \quad (38)$$

Among them, $r_1, r_2 \sim \text{Uniform}(0, 1)$ are random numbers, \odot represents element-wise multiplication, $p_{best,i}$ is the historical best position of particle i , and g_{best} is the global best position. In each iteration, the algorithm adjusts the particle positions using the above update formulas and evaluates the quality of each particle solution through the fitness function, thereby updating the individual historical best $p_{best,i}$ and the global best g_{best} . **Fitness function** $F(x)$ is defined as the negative of the coverage time (converted to a minimization problem):

$$F(x) = -T_{cover}(x) \quad (39)$$

The algorithm continues to iterate until the maximum number of iterations or convergence criteria are met, finally outputting the global optimal solution g_{best} and the corresponding maximum coverage time.

6.2.7 Solution Results

Based on the MATLAB-implemented two-level optimization algorithm (code in the appendix), the optimal deployment strategy is as follows:

The UAV flies at a heading angle of 176.91° , a speed of 72 m/s, drops at 0 s, detonates after 2.4991 s, with an effective coverage time of 4.738 s, as shown in Figure 8. Compared to the 1.4 s in Problem 1, this is an improvement of 238%.

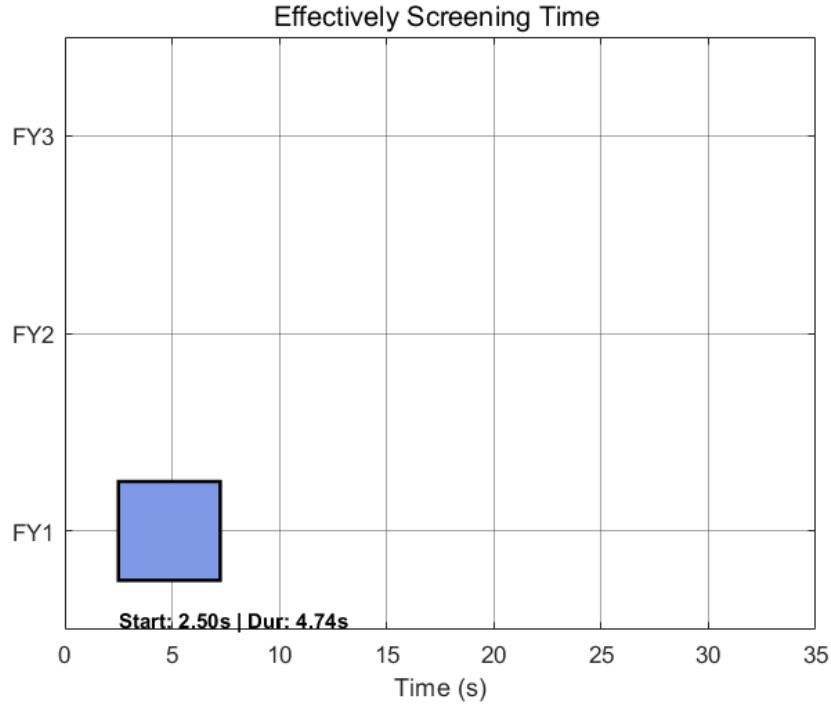

Figure 8: the results of Problem 2

6.3 Problem 3 Solution: Multi-Projectile Coordination Strategy

In this problem, the UAV FY1 needs to continuously deploy 3 smoke grenades to interfere with missile M1. Unlike deploying a single smoke grenade, the deployment strategy for three smoke grenades involves temporal coordination, with the core issue being the optimization of multiple parameters to maximize the smoke grenade coverage time.

6.3.1 Decision Variables

According to the problem requirements, once the UAV receives the mission, its speed and heading are fixed and no longer adjusted. Therefore, in mission decision-making, we need to decide the following eight variables 3: Flight speed v_{FY_1} , flight heading angle α , drop times $t_{drop,i}$ ($i \in \{1, 2, 3\}$), delayed detonation times $t_{delay,i}$, ($i \in \{1, 2, 3\}$), thereby defining the decision vector \mathbf{X} :

$$\mathbf{X} = [v_{FY_1}, \alpha, t_{drop,1}, t_{drop,2}, t_{drop,3}, t_{delay,1}, t_{delay,2}, t_{delay,3}]^T \in \mathbb{R}^8 \quad (40)$$

Table 3: Decision Variables and Constraints for Problem 3

| Variable Type | Specific Variable | Constraint Range |
|--------------------------|-------------------|--------------------------|
| Global Flight Parameters | v_{FY_1} | [70, 140] m/s |
| | α | $[0, 2\pi)$ rad |
| | $t_{drop,1}$ | [0, 12] s |
| Drop Times | $t_{drop,2}$ | $[t_{drop,1} + 1, 12]$ s |
| | $t_{drop,3}$ | $[t_{drop,2} + 1, 12]$ s |
| | $t_{delay,1}$ | [1, 8] s |
| Delayed Detonation Times | $t_{delay,2}$ | [1, 8] s |
| | $t_{delay,3}$ | [1, 8] s |
| | | |

6.3.2 Multi-Projectile Motion State Equations

Based on the single projectile motion model established in Problem 1, it is extended to a multi-projectile scenario. The motion state of the k -th smoke grenade is described by the following equations:

1. Drop Point Coordinates:

$$P_{drop,k}(\mathbf{X}) = B_0 + \mathbf{v}_{FY_1}(v_{FY_1}, \alpha) \cdot t_{drop,k} \quad (41)$$

2. Burst Point Coordinates:

$$P_{burst,k}(\mathbf{X}) = P_{drop,k}(\mathbf{X}) + \mathbf{v}_{FY_1}(v_{FY_1}, \alpha) \cdot t_{delay,k} + \left[0, 0, -\frac{1}{2}gt_{delay,k}^2 \right]^T \quad (42)$$

3. Smoke Cloud Center Trajectory: After the burst time $t_{burst,k} = t_{drop,k} + t_{delay,k}$, the position of the k -th cloud center is

$$P_{S,k}(t) = P_{burst,k} - [0, 0, v_{cloud} \cdot (t - t_{burst,k})]^T, \quad t \in [t_{burst,k}, t_{burst,k} + 20] \quad (43)$$

This time window $[t_{burst,k}, t_{burst,k} + 20]$ represents the effective duration of the k -th smoke grenade being 20 seconds.

6.3.3 Objective Function

Define the coverage state of the k -th smoke grenade at time t as:

$$I_k(t; \mathbf{X}) = \begin{cases} 1, & D_k(t) \leq R_{cloud} \text{ and } t \in [t_{burst,k}, t_{burst,k} + 20] \\ 0, & \text{otherwise} \end{cases} \quad (44)$$

Here, $D_k(t)$ is the shortest distance from the center of the k -th smoke cloud to the line of sight between missile M_1 and target P_T . **System Total Coverage State (Logical OR)** Since the three smoke clouds may exist simultaneously, the system coverage state at time t is defined as the **logical OR**:

$$I_{total}(t; \mathbf{X}) = \bigvee_{k=1}^3 I_k(t; \mathbf{X}) \quad (45)$$

Here, $\bigvee_{k=1}^3$ is the logical OR operator. The physical meaning of this definition is: as long as **at least one** smoke grenade is effectively covering, the missile is considered to be in

a covered state ($I_{total} = 1$). The final optimization objective is to maximize the total effective coverage duration T_{cover} defined as the time integral of the indicator function:

$$\max J(\mathbf{X}) = T_{cover}(\mathbf{X}) = \int_0^{T_{end}} I_{total}(t; \mathbf{X}) dt \quad (46)$$

This integral actually calculates the **union length** of the coverage time intervals. For example, if smoke grenade 1 is effective during [5, 8] seconds and smoke grenade 2 is effective during [7, 10] seconds, the union is [5, 10], with a total duration of 5 seconds, not $3 + 3 = 6$ seconds.

6.3.4 Constraints

Basic boundary constraints:

$$\begin{cases} 70 \leq v_{FY_1} \leq 140 & \text{(Velocity Range)} \\ 0 \leq \alpha < 2\pi & \text{(Heading Angle)} \\ 0 < t_{drop,1} < t_{drop,2} < t_{drop,3} \leq 12 & \text{(Drop Time Order)} \\ 1 \leq t_{delay,k} \leq 8, \quad k = 1, 2, 3 & \text{(Detonation Delay Range)} \end{cases} \quad (47)$$

Height constraint: each smoke grenade must detonate in the air

$$z_{burst,k}(\mathbf{X}) > 0, \quad k = 1, 2, 3 \quad (48)$$

Besides satisfying flight and height constraints, this problem must strictly satisfy the operational interval constraints between multiple projectiles. The problem requires that each drone must have at least a 1-second interval between deploying two smoke grenades to prevent mechanical interference caused by consecutive deployments, ensuring the drone has enough time to adjust its posture and avoid collisions between smoke grenades in the air.

$$t_{drop,k+1} - t_{drop,k} \geq 1, \quad k = 1, 2 \quad (49)$$

6.3.5 Model Summary

The multi-projectile collaborative optimization model for Problem 3 can be summarized as:

$$\left\{
 \begin{array}{l}
 \text{Decision Variables: } \mathbf{X} = [v_{FY_1}, \alpha, t_{drop,1}, t_{drop,2}, t_{drop,3}, t_{delay,1}, t_{delay,2}, t_{delay,3}]^T \\
 \text{Objective Function: } \max T_{cover}(\mathbf{X}) = \int_0^{T_{end}} I_{total}(t; \mathbf{X}) dt \\
 \text{State Equations: } \begin{cases} P_{drop,k} = P_{FY_1}(0) + \mathbf{v}_{FY_1} \cdot t_{drop,k} \\ P_{burst,k} = P_{drop,k} + \mathbf{v}_{FY_1} \cdot t_{delay,k} + [0, 0, -\frac{1}{2}gt_{delay,k}^2]^T \\ P_{S,k}(t) = P_{burst,k} - [0, 0, v_{cloud}(t - t_{burst,k})]^T, \quad k = 1, 2, 3 \end{cases} \\
 \text{Coverage Union: } I_{total}(t; \mathbf{X}) = \bigvee_{k=1}^3 I_k(t; \mathbf{X}) \\
 \text{Constraints: } \begin{cases} 70 \leq v_{FY_1} \leq 140 \\ 0 < t_{drop,1} < t_{drop,2} < t_{drop,3} \leq 12 \\ t_{drop,k+1} - t_{drop,k} \geq 1, \quad k = 1, 2 \\ 1 \leq t_{delay,k} \leq 8, \quad k = 1, 2, 3 \\ z_{burst,k}(\mathbf{X}) > 0, \quad k = 1, 2, 3 \end{cases}
 \end{array}
 \right. \tag{50}$$

6.3.6 Solution Algorithm

For the problem with increased decision variable dimensions (from 4 to 8) and temporal logic constraints, we continue to use the two-layer optimization framework of grid scanning + particle swarm optimization (PSO) from Problem 2.

Outer layer: grid scanning of velocity $v_{FY_1} \in [70, 140]$ with a step size of 0.5 m/s

Inner layer: improved particle swarm optimization (PSO with Catastrophe) to optimize the remaining 7 variables

Inner Layer Algorithm Improvement Due to the 8-dimensional problem being much more complex than the 4-dimensional one, traditional PSO is prone to local optima or convergence stagnation. This paper introduces the **Catastrophe Mechanism** to enhance global exploration capability.

Stagnation Detection: If the global best solution does not improve for 15 consecutive generations, it is considered stagnation.

$$\text{stagnation_counter} \geq 15 \Rightarrow \text{Trigger Catastrophe} \tag{51}$$

Catastrophe Operation:

1. Retain the top 50% elite particles (best fitness)
2. Randomly reinitialize the remaining 50% particles in the search space
3. Reset the historical best p_{best} , but retain the global best g_{best}

This mechanism is similar to restarting the search and effectively avoids premature convergence. To automatically satisfy the dropping interval constraint $t_{drop,k+1} - t_{drop,k} \geq 1$,

incremental encoding is used instead of direct encoding:

Particle Encoding:

$$X_{particle} = [\alpha, t_{drop,1}, \Delta t_1, \Delta t_2, t_{delay,1}, t_{delay,2}, t_{delay,3}]^T \quad (52)$$

where $\Delta t_1, \Delta t_2 \geq 0$ are time increments.

Decoding Method:

$$t_{drop,2} = t_{drop,1} + 1.0 + \Delta t_1, \Delta t_1 \geq 0 \quad (53)$$

$$t_{drop,3} = t_{drop,2} + 1.0 + \Delta t_2 = (t_{drop,1} + 2.0 + \Delta t_1 + \Delta t_2), \Delta t_2 \geq 0 \quad (54)$$

This encoding method essentially embeds the constraint, ensuring any particle automatically satisfies the interval ≥ 1 s.

Fitness Function

$$F(\mathbf{X}) = -T_{cover}(\mathbf{X}) + \lambda \sum_{k=1}^3 \max(0, -z_{burst,k})^2 \quad (55)$$

The first term is negated to convert to minimization, and the second term is a quadratic penalty for the altitude constraint ($\lambda = 10^6$).

Algorithm Parameters

Outer layer scanning: 140 velocity points

Particle swarm size: $N = 50$

Maximum iterations: $G_{max} = 300$

Inertia weight: $w = 0.8$

Learning factors: $c_1 = c_2 = 1.5$

Time step: $\Delta t = 0.05$ s

6.3.7 Solution Results

According to the above process, we use the improved particle swarm optimization algorithm with the catastrophe mechanism to obtain the UAV FY1 heading angle of $0.1543rad(8.84)$, speed of $101.88m/s$, corresponding to the maximum effective shielding time of 6.45s. The optimal strategy for deploying 3 smoke grenades to interfere with missile M1 is shown in Figure 9, and the specific deployment strategies of the three smoke grenades are shown in Table 4. Analyzing this result, we find that smoke grenade 2 is effective in $[1.0, 4.16]$ seconds, smoke grenade 1 takes over in $[4.77, 6.93]$ seconds, achieving partial temporal coverage continuity, but smoke grenade 3 did not play a role.

Table 4: Problem 3 Strategy Table

| Smoke Grenade No. | UAV Heading (rad) | UAV Speed (m/s) | Drop Coordinates (m) | | | Detonation Coordinates (m) | | |
|-------------------------|-------------------------|-----------------------|----------------------|-------|------|----------------------------|-------|-------|
| | | | X | Y | Z | X | Y | Z |
| 1 | 0.1543 (8.84°) | 101.88 | 17800 | 0 | 1800 | 17800 | 0 | 1800 |
| 2 | 0.1543 (8.84°) | 101.88 | 17900.7 | 15.7 | 1800 | 17900.7 | 15.7 | 1800 |
| 3 | 0.1543 (8.84°) | 101.88 | 18792.6 | 154.4 | 1800 | 20302.6 | 389.2 | 697.5 |

| Smoke Grenade No. | Effective Interference Duration (s) | Effective Time (s) | | Expiration Time (s) |
|-------------------------|--|--------------------|-----|---------------------|
| | | Start | End | |
| 1 | 2.63 | 4.77 | | 7.4 |
| 2 | 4.16 | 1.00000 | | 5.16 |
| 3 | 0.00000 | 0.00000 | | 0.00000 |

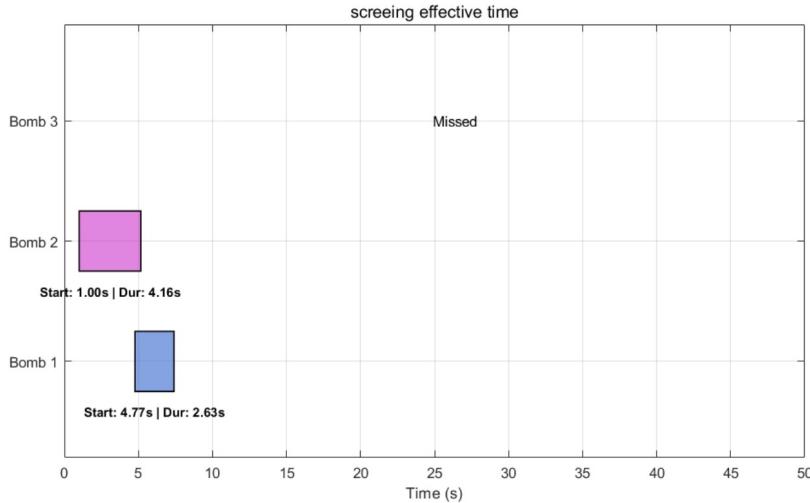

Figure 9: Problem 3 Results

6.4 Problem 4 Solution: Multi-UAV Collaborative Optimization

In Problems 1 to 3, we studied the issue of a single UAV adjusting its own flight path and bomb deployment strategy to shield and intercept a single incoming missile. In Problem 4, the task changes to three UAVs FY_1, FY_2, FY_3 , each deploying a smoke grenade to jointly intercept missile $M1$. Due to the different initial positions of the three UAVs, they are located in different areas of the battlefield. This spatial layout results in different distances and azimuth angles from each UAV to the missile's initial position, true target position, and decoy target position, requiring tailored flight strategies for each UAV. To maximize the total shielding time, ideally, the three smoke grenades form a **seamless relay** on the timeline, meaning the expiration time of the first smoke grenade exactly connects to the effective time of the second. This requires fine coordination of each UAV's drop time $t_{drop,i}$ and detonation delay $t_{delay,i}$, so that the spatial positions and

time windows of the smoke clouds can achieve perfect coordination. Meanwhile, compared to the 4-dimensional decision space in Problem 2 and the 8-dimensional decision space in Problem 3, the decision dimension in Problem 4 rises to 12 dimensions, with the search space growing exponentially and interactions and mutual influences among the dimensions. Therefore, the core issue lies in coordinating the bomb deployment strategies of the three UAVs located in different spatial positions.

6.4.1 Decision Variables

According to the problem requirements, once a UAV receives a mission, its speed and heading are fixed and no longer adjusted. Therefore, when making mission decisions, we need to decide on 12 variables: The system contains 3 independent moving entities (UAVs). Define $i \in 1, 2, 3$ corresponding to FY_1, FY_2, FY_3 respectively. Each entity's decision vector \mathbf{u}_i contains 4 parameters:

$$\mathbf{u}_i = [v_{FY_i}, \alpha_i, t_{drop,i}, t_{delay,i}] \quad (56)$$

The physical meanings of each parameter are shown in the following table:

Table 5: Description of Decision Variables in Problem 4

| Parameter | Meaning | Description |
|---------------|---|--|
| v_{FY_i} | Flight speed of the i -th UAV | Affects the UAV's maneuverability and the time to reach the drop point, range $[70, 140]$ m/s |
| α_i | Heading angle of the i -th UAV | Determines the UAV's flight direction, directly influencing the spatial position of the drop point, range $[0, 2\pi]$ rad |
| $t_{drop,i}$ | Drop time of the smoke grenade by the i -th UAV | Determines the release timing of the smoke grenade, affecting overall temporal coordination; UAVs in different positions require different drop time windows |
| $t_{delay,i}$ | Detonation delay of the i -th smoke grenade | Controls the generation height and spatial position of the smoke cloud, range $[1, 8]$ s |

The global decision vector \mathbf{X} contains 12 dimensions:

$$\mathbf{X} = [\mathbf{u}_1, \mathbf{u}_2, \mathbf{u}_3] = [v_1, \alpha_1, t_{drop,1}, t_{delay,1}, \dots, v_3, \alpha_3, t_{drop,3}, t_{delay,3}]^T \quad (57)$$

6.4.2 State Equations

The initial positions of each UAV $\mathbf{Pos}_{UAV,i}$ are different, The i -th UAV flies at speed v_{FY_i} and heading α_i for $t_{drop,i}$ seconds to reach the drop point $P_{drop,i}$

$$P_{drop,i} = \mathbf{Pos}_{UAV,i} + \mathbf{v}_{FY_i} \cdot t_{drop,i} \quad (58)$$

The smoke grenade starts from the drop point, flies inertially with the UAV for $t_{delay,i}$ seconds before detonating, and simultaneously descends under gravity. The detonation position $P_{burst,i}$ is:

$$P_{burst,i} = P_{drop,i} + \mathbf{v}_{FY_i} \cdot t_{delay,i} + [0, 0, -\frac{1}{2}gt_{delay,i}^2]^T \quad (59)$$

After detonation, the smoke cloud descends vertically at a settling velocity of $v_{cloud} = 3$ m/s. Its center trajectory $P_{S,i}(t)$ is given by

$$P_{S,i}(t) = P_{burst,i} - [0, 0, v_{cloud} \cdot (t - t_{burst,i})]^T \quad (60)$$

6.4.3 Objective Function

Since the 3 smoke clouds may exist simultaneously and cause shielding effects, the total shielding time cannot be simply summed, but should be calculated as the union on the time axis. Define the shielding indicator function $I_{i,k,j}(t)$ of the k -th smoke cloud from the i -th aircraft on missile j .

Then the total shielding state $S_1(t)$ of the system in this problem is the logical OR of each sub-state:

$$S_1(t) = \bigvee_{i=1}^3 I_{i,1,1}(t) \quad (61)$$

The final optimization objective function is defined as minimizing the cost $J(\mathbf{X})$:

$$\min J(\mathbf{X}) = - \left(\int_0^{T_{end}} S_1(t) dt \right) + \lambda \cdot \sum_{i=1}^3 \max(0, d_{min,i} - R_{cloud}) \quad (62)$$

Where: The first term represents the total shielding duration (negated for minimization), The second term is a penalty term, where $d_{min,i}$ is the minimum distance of the i -th smoke grenade to the line of sight during its lifecycle, and $\lambda = 0.1$ is the weighting coefficient. When the smoke grenade completely misses the target, this term penalizes the distance to force the solution closer to the line of sight.

6.4.4 Constraints

Speed constraints: These constraints are determined by the physical performance of the UAVs and are given by the problem

$$70 \leq v_{FY_i} \leq 140, \quad \forall i \quad (63)$$

Time window constraints: Considering that missile M_1 flies from $(20000, 0, 2000)$ to the false target $(0, 0, 0)$ at a speed of 300 m/s, the total flight time is approximately 66.7 s. During this period, the first smoke grenade should be effective in the early stage of the missile flight ($0 \sim 15$ s), the second in the middle stage ($15 \sim 35$ s), and the third in the later stage ($35 \sim 55$ s) to continue the shielding.

$$t_{drop,1} \leq 15, \quad t_{drop,2} \leq 35, \quad t_{drop,3} \leq 55 \quad (64)$$

Detonation delay constraints: These constraints ensure that the smoke grenades have sufficient inertial flight distance (at least $70 \times 1 = 70$ m) while avoiding too low detonation heights (excessive delay may cause the smoke grenades to hit the ground).

$$1 \leq t_{delay,i} \leq 8 \quad (65)$$

Height constraints: Ensure that the detonation height of all smoke grenades is non-negative to avoid physically unreasonable solutions of underground detonation.

$$z_{burst,i}(\mathbf{X}) \geq 0, \quad i = 1, 2, 3 \quad (66)$$

6.4.5 Model Summary

The multi-UAV collaborative optimization model for Problem 4 can be systematically represented as:

$$\left\{ \begin{array}{l} \text{Decision Variables: } \mathbf{X} = [\mathbf{u}_1, \mathbf{u}_2, \mathbf{u}_3]^T, \quad \mathbf{u}_i = [v_{FY_i}, \alpha_i, t_{drop,i}, t_{delay,i}] \\ \text{Objective Function: } \min J(\mathbf{X}) = - \int_0^{T_{end}} S_1(t) dt + \lambda \sum_{i=1}^3 \max(d_{min,i} - R_{cloud}, 0) \\ \text{State Equations: } \begin{cases} \mathbf{v}_{FY_i} = [v_{FY_i} \cos \alpha_i, v_{FY_i} \sin \alpha_i, 0]^T \\ P_{drop,i} = \mathbf{Pos}_{UAV,i} + \mathbf{v}_{FY_i} \cdot t_{drop,i} \\ P_{burst,i} = P_{drop,i} + \mathbf{v}_{FY_i} \cdot t_{delay,i} + [0, 0, -\frac{1}{2}gt_{delay,i}^2]^T \\ P_{S,i}(t) = P_{burst,i} - [0, 0, v_{cloud}(t - t_{burst,i})]^T, \quad i = 1, 2, 3 \end{cases} \\ \text{Shielding Union: } S_1(t) = \bigvee_{i=1}^3 I_{i,1,1}(t) \\ \text{Constraints: } \begin{cases} 70 \leq v_{FY_i} \leq 140, \quad i = 1, 2, 3 \\ t_{drop,1} \leq 15, \quad t_{drop,2} \leq 35, \quad t_{drop,3} \leq 55 \\ 1 \leq t_{delay,i} \leq 8, \quad i = 1, 2, 3 \\ z_{burst,i}(\mathbf{X}) \geq 0, \quad i = 1, 2, 3 \end{cases} \end{array} \right. \quad (67)$$

6.4.6 Solution Algorithm

Due to the increase in the dimensionality of decision variables to 12 dimensions, and the significant differences among these dimensions, the Differential Evolution (DE) algorithm, which does not require continuity or differentiability of the objective function, can handle complex optimization problems that are non-convex, multi-modal, and high-dimensional. Even in the presence of local optima, the differential mutation mechanism can maintain population diversity and escape local traps. The DE algorithm performs mutation based on differential vectors, adaptively adjusts the search step size, and is insensitive to variable scale differences. There is no need to normalize decision variables. The DE algorithm evaluates multiple candidate solutions in parallel within the population, enabling simultaneous exploration of multiple regions in the decision space, making it suitable for multi-UAV collaborative combinatorial optimization problems. Compared to Genetic Algorithms (GA), the mutation strategy of DE is more efficient and typically finds high-quality solutions in fewer iterations.

Algorithm Flow Design

- **Population Initialization:**

Generate an initial population of $NP = 200$ individuals. For the heading angle α_i , perform **normal distribution initialization** based on the initial line-of-sight angle $\theta_{base,i}$ from each UAV to the dummy target, controlling the range within $[\theta_{base,i} - 45, \theta_{base,i} + 45]$ to improve search efficiency.

- Initialization Strategy Explanation:**

- For the i -th UAV, calculate the azimuth angle from its initial position $\mathbf{Pos}_{UAV,i}$ to the dummy target $(0, 0, 0)$:

$$\theta_{base,i} = \arctan 2(0 - y_{UAV,i}, 0 - x_{UAV,i}) \quad (68)$$

- Sample the heading angle α_i near $\theta_{base,i}$, so that the initial heading of the UAV roughly points towards the dummy target direction, narrowing the search range.
- Other variables (speed, drop time, delay) are uniformly randomly sampled within their constraint ranges to ensure diversity of the initial population.

- **Mutation:**

Use the **DE/rand/1** strategy to generate the mutation vector \mathbf{V}_g :

$$\mathbf{V}_{i,g} = \mathbf{X}_{r_1,g} + F \cdot (\mathbf{X}_{r_2,g} - \mathbf{X}_{r_3,g}) \quad (69)$$

where r_1, r_2, r_3 are three mutually distinct individual indices randomly selected from the current population (and all not equal to i), and F is the scaling factor.

Adaptive Scaling Factor: To balance global exploration and local exploitation, the scaling factor F adopts a **linear decay strategy**

$$F(g) = F_{max} - \frac{(F_{max} - F_{min}) \cdot g}{G_{max}} \quad (70)$$

where $F_{max} = 0.5$, $F_{min} = 0$, g is the current iteration number, and $G_{max} = 800$ is the maximum number of iterations. A larger F value in the early stages helps global exploration, while a smaller F value in later stages aids in fine local search.

- **Crossover:**

Perform **binomial crossover** between the mutation vector $\mathbf{V}_{i,g}$ and the target vector $\mathbf{X}_{i,g}$ to generate the trial vector $\mathbf{U}_{i,g}$:

$$U_{i,g}^{(j)} = \begin{cases} V_{i,g}^{(j)}, & \text{if } \text{rand}(0, 1) \leq CR \text{ or } j = j_{rand} \\ X_{i,g}^{(j)}, & \text{otherwise} \end{cases} \quad (71)$$

where $j \in \{1, 2, \dots, 12\}$ is the dimension index, $CR = 0.9$ is the crossover probability, and j_{rand} is a randomly selected dimension (ensuring at least one dimension comes from the mutation vector).

High Crossover Rate Choice: $CR = 0.9$ means about 90% of the dimensions come from the mutation vector, which can fully utilize the differential information of the population and accelerate convergence.

- **Selection:**

Calculate the fitness of the trial vector and the target vector, and use a **greedy strategy** to select the individual with better fitness to enter the next generation:

$$\mathbf{X}_{i,g+1} = \begin{cases} \mathbf{U}_{i,g}, & \text{if } J(\mathbf{U}_{i,g}) < J(\mathbf{X}_{i,g}) \\ \mathbf{X}_{i,g}, & \text{otherwise} \end{cases} \quad (72)$$

This selection mechanism ensures that the average fitness of the population monotonically decreases (for minimization problems), preventing degradation.

- **Termination Condition:**

Reach the maximum number of iterations $G_{max} = 800$

6.4.7 Solution Results

We solved it using the differential evolution algorithm (DE) in MATLAB. The corresponding three-aircraft collaborative deployment strategy is shown in Table 6, and the effect is depicted in Figure 10. The maximum total effective shielding time was 14.9600 seconds. Meanwhile, there is an approximately 6.45-second gap between the shielding periods of FY_1 and FY_2 ($12.10 - 9.42 = 2.68$ seconds), and there is an approximately 5.28-second gap between FY_2 and FY_3 . This indicates that the three-aircraft collaboration did not achieve perfect seamless succession, and there are two shielding intervals. However, from a global perspective, the total shielding time can reach a larger value, providing a better shielding effect. By observing the coordinates of the deployment points and the initiation points, it can be seen that the smoke grenades of FY_1 form a shielding effect in the early stage of the missile's flight, when the missile is far from the dummy target and the line of sight is longer. The smoke grenades of FY_2 take over in the middle stage of the missile's flight. The smoke grenades of FY_3 continue to shield in the later stage of the missile's flight, when the missile is approaching the dummy target and the line of sight is shorter. This strategy of distributing in the three stages of "front, middle, and rear" fully utilizes the spatial position advantages of the three unmanned aircraft, forming a "successive three-dimensional blockade".

Table 6: Problem 4 Three-Aircraft Collaborative Final Strategy

| Drone | Heading (°) | T_{cover} | Deployment Point (m) | Initiation Point (m) |
|-------|-------------|-------------|--------------------------|-------------------------|
| | | | (X,Y,Z) | (X,Y,Z) |
| FY1 | 178.42 | 4.65 | (17747.32, 1.45, 1800) | (17521.68, 7.68, 1760) |
| FY2 | -129.29 | 4.82 | (11492.56, 779.81, 1400) | (10897.90, 53.01, 1099) |
| FY3 | 106.94 | 5.46 | (5291.39, -673.54, 700) | (5051.65, 113.58, 518) |

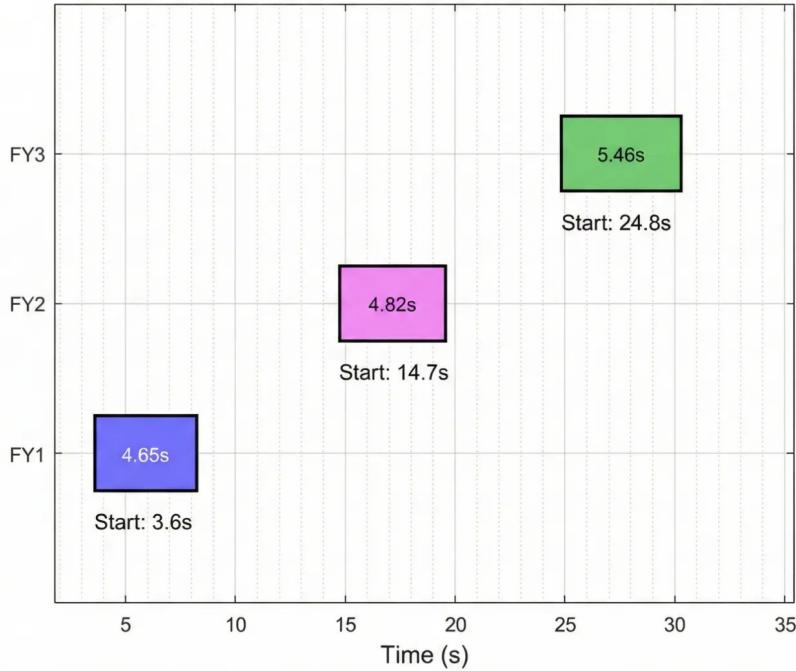

Effective Occlusion Timing Gantt Chart (Total Effective Duration: 14.9600s)

Figure 10: Problem 4 Result

6.5 Problem 5 Solution: Multi-Aircraft Multi-Target Collaborative Interception

Problem 5 extends the combat scenario to **many-to-many collaborative interception**: 5 drones $FY_1 - FY_5$ collaboratively intercept 3 incoming missiles $M_1 - M_3$, each drone can carry up to 3 smoke grenades. Compared to Problem 4, the complexity of Problem 5 exhibits **exponential growth**:

1. Too Many Decision Variables:

If the modeling approach from Problem 4 is used, the number of decision variables to be optimized is:

$$n_{vars} = 5 \times (2 + 3 \times 2) = 5 \times 8 = 40 \text{ dimensions} \quad (73)$$

Each drone needs to decide: speed v_{FY_i} , heading α_i , and the deployment time $t_{drop}^{(i,k)}$ and initiation delay $t_{delay}^{(i,k)}$ of 3 smoke grenades ($k = 1, 2, 3$). Performing global optimization in a 40-dimensional continuous space, even with efficient evolutionary algorithms, a single fitness evaluation requires simulating the trajectories of 5 drones, 15 potential smoke grenades, and 3 missiles over 60 seconds, with a computational complexity of approximately $O(5 \times 15 \times 3 \times 1200) = O(2.7 \times 10^5)$ basic operations. If the population size is 200 and the number of iterations is 1000, the total computational load will reach $O(5.4 \times 10^{10})$.

2. Multi-Objective Coupling:

Unlike the single missile interception in Problem 4, Problem 5 requires simultaneously shielding 3 missiles. This introduces a resource allocation problem: How should the 15 smoke grenades of 5 drones be allocated

among the 3 missiles, and which missile should a particular drone prioritize for interception?

3. **Spatiotemporal Coordination Complexity:** The initial positions and flight directions of the 3 missiles differ, and the 5 drones are distributed in different areas of the battlefield. A drone at a certain spatial position may be advantageous for missile M_1 , but not for M_2 or M_3 . Therefore, joint optimization is required in the three dimensions of **space, time, and target allocation**.

To address the above complexity challenges, this paper adopts a **hierarchical decoupling strategy**—decomposing the 40-dimensional highly coupled optimization problem into:

- **Outer Layer (Strategic Layer):** Optimize the flight parameters (speed, heading) of 5 drones, reducing the decision dimension to 10.
- **Inner Layer (Tactical Layer):** Given the flight trajectories, automatically generate the optimal bomb deployment scheme for each drone (including target allocation, deployment time, and initiation delay) through heuristic algorithms.

This hierarchical architecture decouples trajectory planning from timing scheduling, significantly reducing the search space dimension while maintaining solution quality.

Strategic Decision Variables (Outer Layer) Define the global flight decision vector X_{fly} , including the speed and heading of 5 drones:

$$X_{fly} = [v_1, \alpha_1, v_2, \alpha_2, \dots, v_5, \alpha_5]^T \in \mathbb{R}^{10} \quad (74)$$

The physical meanings of each variable are as follows:

Table 7: Strategic Decision Variables for Problem 5

| Parameter | Meaning | Description |
|------------|------------------------------|---|
| v_{FY_i} | Speed of the i -th drone | Determines the maneuvering range and the time to reach key positions, range $[70, 140]$ m/s |
| α_i | Heading of the i -th drone | Determines the flight direction, directly affecting the spatial coverage and the set of interceptable missiles, range $[0, 2\pi]$ rad |

Optimizing flight parameters (10 dimensions) instead of directly optimizing all bomb deployment parameters (40 dimensions) significantly reduces the complexity of the search space.

Tactical Decision Variables (Inner Layer Generation) For the i -th drone, the deployment parameters of its k -th smoke grenade ($k = 1, 2, 3$) are **not used as outer layer optimization variables**, but are automatically generated in the inner layer through heuristic algorithms:

$$u_{i,k} = \left[t_{drop}^{(i,k)}, t_{delay}^{(i,k)}, m_{target}^{(i,k)} \right] \quad (75)$$

where $m_{target}^{(i,k)} \in \{1, 2, 3\}$ is the target missile number intercepted by this smoke grenade. Given the flight trajectories X_{fly} determined by the outer layer, the inner layer algorithm traverses all possible combinations of bomb deployment times and initiation delays, evaluates the shielding effect of each combination on the 3 missiles, and selects the 3 bomb deployments with the maximum total shielding time through a greedy strategy (see the subsequent "Solution Algorithm" section for details).

6.5.1 State Space

Multi-Missile Motion Model The initial positions and flight characteristics of the 3 missiles M_1 , M_2 , and M_3 are given by the problem:

$$\begin{aligned} M_1 : \mathbf{P}_{M_1}(0) &= (20000, 0, 2000), \quad \mathbf{n}_{M_1} = \frac{(0, 0, 0) - \mathbf{P}_{M_1}(0)}{\| \dots \|} \\ M_2 : \mathbf{P}_{M_2}(0) &= (19000, 600, 2100), \quad \mathbf{n}_{M_2} = \frac{(0, 0, 0) - \mathbf{P}_{M_2}(0)}{\| \dots \|} \\ M_3 : \mathbf{P}_{M_3}(0) &= (18000, -600, 1900), \quad \mathbf{n}_{M_3} = \frac{(0, 0, 0) - \mathbf{P}_{M_3}(0)}{\| \dots \|} \end{aligned} \quad (76)$$

All missiles fly at a constant speed of $V_m = 300$ m/s in a straight line towards the dummy target at $(0, 0, 0)$, with the motion equation:

$$\mathbf{P}_{M_j}(t) = \mathbf{P}_{M_j}(0) + V_m \mathbf{n}_{M_j} t, \quad j = 1, 2, 3 \quad (77)$$

Multi-Drone Motion Model The initial positions of the 5 drones are given by the problem, and the motion equations are similar to those in Problem 4:

$$\mathbf{P}_{FY_i}(t) = \mathbf{P}_{FY_i}(0) + \mathbf{v}_{FY_i} t, \quad i = 1, \dots, 5 \quad (78)$$

where $\mathbf{v}_{FY_i} = [v_{FY_i} \cos \alpha_i, v_{FY_i} \sin \alpha_i, 0]^T$ is the velocity vector of the i -th drone.

Smoke Grenade Motion Model The motion process of the k -th smoke grenade deployed by the i -th drone is:

$$\begin{aligned} \text{Drop Point: } P_{drop}^{(i,k)} &= \mathbf{P}_{FY_i}(t_{drop}^{(i,k)}) \\ \text{Burst Point: } P_{burst}^{(i,k)} &= P_{drop}^{(i,k)} + \mathbf{v}_i t_{delay}^{(i,k)} + [0, 0, -\frac{1}{2} g(t_{delay}^{(i,k)})^2]^T \\ \text{Cloud Trajectory: } P_S^{(i,k)}(t) &= P_{burst}^{(i,k)} - [0, 0, v_{cloud}(t - t_{burst}^{(i,k)})]^T \end{aligned} \quad (79)$$

where $t_{burst}^{(i,k)} = t_{drop}^{(i,k)} + t_{delay}^{(i,k)}$ is the burst time, and $v_{cloud} = 3$ m/s is the sinking speed. Define the shielding indicator function of the k -th smoke grenade of the i -th drone against the j -th missile:

$$I_{i,k,j}(t) = \begin{cases} 1, & \text{if } d(P_S^{(i,k)}(t), L_{M_j}(t)) \leq R_{cloud} \text{ and } t \in [t_{burst}^{(i,k)}, t_{burst}^{(i,k)} + T_{life}] \\ 0, & \text{otherwise} \end{cases} \quad (80)$$

where $L_{M_j}(t)$ is the line of sight of missile M_j towards the true target, $d(P_S^{(i,k)}(t), L_{M_j}(t))$ represents the distance between the current position of the k -th smoke grenade of the i -th drone and the missile's line of sight, $R_{cloud} = 10$ m, and $T_{life} = 20$ s.

6.5.2 Objective Function

Due to the existence of 3 independent interception targets, the total system benefit is defined as the **sum of the effective shielding durations of all missiles**. For the j -th missile ($j = 1, 2, 3$), its shielding state $S_j(t)$ is the **logical OR** of all possible shielding sources:

$$S_j(t) = \bigvee_{i=1}^5 \bigvee_{k=1}^3 I_{i,k,j}(t) = \max_{i,k} \{I_{i,k,j}(t)\} \quad (81)$$

The total shielding time $T_{cover,j}$ of the j -th missile is:

$$T_{cover,j} = \int_0^{T_{end}} S_j(t) dt \quad (82)$$

The final optimization objective is to **maximize the total benefit**:

$$\max J(X_{fly}) = \sum_{j=1}^3 T_{cover,j} = \sum_{j=1}^3 \left(\int_0^{T_{end}} S_j(t) dt \right) \quad (83)$$

Union Calculation Explanation

- For a single missile M_j , it may be shielded simultaneously by multiple drones and multiple smoke grenades. For example, at time $t = 10$ s, if the 1st smoke grenade of FY_1 and the 2nd smoke grenade of FY_2 both shield M_1 , it still counts as 1 second of shielding time (not 2 seconds).
- Therefore, it is necessary to calculate the union of shielding on the time axis for each missile separately, and then sum them. This is consistent with the union calculation principle in Problems 3 and 4, but extended to a multi-target scenario.
- In actual calculations, discrete time steps (with step size $\Delta t = 0.05$ s) are used. The total number of time steps where $S_j(t) = 1$ is counted, and then multiplied by Δt to obtain the total shielding time.

6.5.3 Constraints

Maximum payload constraint: Each drone can deploy up to $N \leq 3$ smoke grenades, so define the indicator function $\mathbb{1}_{drop}^{(i,k)}$ to represent whether the i -th drone deploys the k -th smoke grenade, satisfying

$$\sum_{k=1}^3 \mathbb{1}_{drop}^{(i,k)} \leq 3, \quad i = 1, \dots, 5 \quad (84)$$

Drop interval constraint:

$$|t_{drop}^{(i,k)} - t_{drop}^{(i,k-1)}| \geq 1, \forall k > 1 \quad (85)$$

Flight boundary constraint:

$$70 \leq v_{FY_i} \leq 140, 0 \leq \alpha_i \leq 2\pi \quad (86)$$

Height constraint: The detonation height of all smoke grenades must be non-negative

$$z_{burst}^{(i,k)} \geq 0, \quad \forall i, k \quad (87)$$

6.5.4 Model Summary

The complete mathematical expression of the multi-drone multi-target cooperative interception optimization model for Problem 5 is:

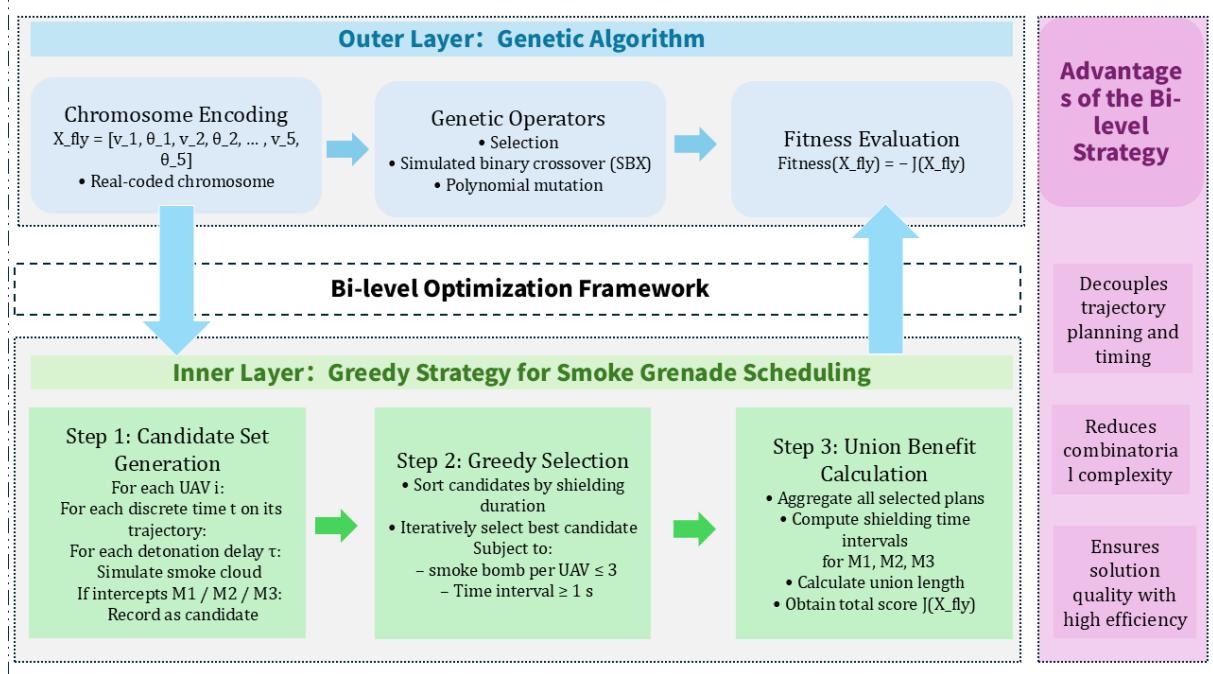

$$\left\{ \begin{array}{l} \text{Decision variables: } X_{fly} = [v_1, \alpha_1, v_2, \alpha_2, \dots, v_5, \alpha_5]^T \\ \text{Objective function: } \max J(X_{fly}) = \sum_{j=1}^3 \int_0^{T_{end}} S_j(t) dt \\ \text{Missile motion: } \mathbf{P}_{M_j}(t) = \mathbf{P}_{M_j}(0) + V_m \mathbf{n}_{M_j} t, \quad j = 1, 2, 3 \\ \text{Drone motion: } \begin{cases} \mathbf{v}_i = [v_{FY_i} \cos \alpha_i, v_{FY_i} \sin \alpha_i, 0]^T \\ \mathbf{P}_{FY_i}(t) = \mathbf{P}_{FY_i}(0) + \mathbf{v}_i t, \quad i = 1, \dots, 5 \end{cases} \\ \text{Smoke grenade motion: } \begin{cases} P_{drop}^{(i,k)} = \mathbf{P}_{FY_i}(t_{drop}^{(i,k)}) \\ P_{burst}^{(i,k)} = P_{drop}^{(i,k)} + \mathbf{v}_i t_{delay}^{(i,k)} + [0, 0, -\frac{1}{2}g(t_{delay}^{(i,k)})^2]^T \\ P_S^{(i,k)}(t) = P_{burst}^{(i,k)} - [0, 0, v_{cloud}(t - t_{burst}^{(i,k)})]^T \end{cases} \quad (88) \\ \text{Shielding state: } S_j(t) = \bigvee_{i=1}^5 \bigvee_{k=1}^3 I_{i,k,j}(t), \quad j = 1, 2, 3 \\ \text{Constraints: } \begin{cases} 70 \leq v_{FY_i} \leq 140, \quad 0 \leq \alpha_i \leq 2\pi, \quad i = 1, \dots, 5 \\ \sum_{k=1}^3 \mathbb{1}_{drop}^{(i,k)} \leq 3, \quad i = 1, \dots, 5 \\ |t_{drop}^{(i,k)} - t_{drop}^{(i,k-1)}| \geq 1, \quad \forall i, k > 1 \\ z_{burst}^{(i,k)} \geq 0, \quad \forall i, k \end{cases} \end{array} \right.$$

where $\mathbb{1}_{drop}^{(i,k)}$ is an indicator function representing whether the i -th drone deploys the k -th smoke grenade; \bigvee denotes the logical OR operation.

6.5.5 Solution Algorithm

For the high-dimensional combinatorial optimization problem of 5 drones and 3 bombs, a two-level optimization structure is still used. The outer layer uses a genetic algorithm to search for the optimal flight parameters of the drones, and the inner layer uses a greedy heuristic algorithm to quickly calculate the optimal bomb deployment scheme for a given trajectory. The overall process design is shown in Figure 11. At the same time, the proposed two-level framework separates the trajectory planning problem from the time-varying smoke grenade scheduling problem. The outer genetic algorithm focuses on the global positioning of the drones, while the inner greedy strategy can efficiently determine the best detonation time, thereby significantly reducing computational complexity without sacrificing solution quality.

Figure 11: Problem 5 Solution Process

- Outer layer: Genetic algorithm for global optimization Encode the speeds and headings of the 5 drones into a chromosome.

$$X_{fly} = [v_1, \alpha_1, v_2, \alpha_2, \dots, v_5, \alpha_5] \in \mathbb{R}^{10} \quad (89)$$

Use real number encoding, with operators using simulated binary crossover and polynomial mutation, which facilitates the use of local information in continuous space. Simulated binary crossover (SBX) and polynomial mutation can accelerate convergence while maintaining population diversity. Implement encoding X_{fly} , and for each individual X_{fly} in the population, call the inner algorithm to calculate the total shielding time $J(X_{fly})$. The fitness is defined as:

$$\text{Fitness}(X_{fly}) = -J(X_{fly}) \quad (90)$$

The negative sign is taken because the standard framework of genetic algorithms is a **minimization** problem, while our goal is to maximize the shielding time.

Genetic operators

- **Selection:** Tournament Selection with a tournament size of 3. Randomly select 3 individuals from the population and choose the one with the best fitness to enter the mating pool. This selection pressure is moderate, maintaining population diversity while accelerating the propagation of superior genes.
- **Crossover:** Simulated Binary Crossover (SBX) with distribution index $\eta_c = 15$. The SBX operator simulates the effect of single-point crossover in binary encoding, generating offspring near the parents and maintaining search locality.
- **Mutation:** Polynomial Mutation with distribution index $\eta_m = 20$ and mutation probability $p_m = 1/10 = 0.1$ (per variable). Polynomial mutation perturbs the current value of a variable, with the magnitude of perturbation decreasing as the distribution index increases, suitable for fine search.

Algorithm parameters

- Population size: $NP = 150$
- Maximum iterations: $G_{max} = 80$
- Elitism: Retain the top 5 individuals with the best fitness in each generation directly into the next generation
- Inner layer: Greedy strategy to solve the bomb deployment scheme For each individual flight trajectory determined in the population, the inner algorithm calculates the fitness through the following steps:

Step 1: Generate candidate strike sets

For the i -th drone, traverse the discrete time points on its flight path $t_{drop} \in [0, 70]$ (step size 1 second). For each drop time, traverse the possible detonation delays $t_{delay} \in [1, 15]$ (step size 2 seconds).

For each (t_{drop}, t_{delay}) combination, calculate the corresponding smoke grenade detonation point P_{burst} , then check whether the smoke cloud can effectively shield any of M_1, M_2, M_3 . The specific judgment method:

- The descent trajectory of the simulated smoke cloud from the explosion time t_{burst} to $t_{burst} + 20$ seconds
- For each missile M_j , calculate the distance $d(t)$ from the center of the smoke cloud to the missile's line of sight $L_{M_j}(t)$
- If there is a time interval $[t_{start}, t_{end}]$ such that $d(t) \leq 10$ meters, then record this candidate solution

$$\text{Candidate} = [t_{drop}, t_{delay}, j, t_{start}, t_{end}, \Delta t_{cover}] \quad (91)$$

where $\Delta t_{cover} = t_{end} - t_{start}$ is the shielding duration.

After traversal, the candidate set \mathcal{C}_i of the i -th drone contains all possible effective strike schemes.

Step 2: Greedy selection

Sort the candidate set in descending order of shielding duration. Select the schemes with the greatest shielding contribution into the final strategy sequentially, subject to: the number of munitions selected by the drone < 3 ; the time interval between the selected schemes of the drone $\geq 1s$.

Step 3: Calculating the combined benefit

Aggregate the bomb deployment schemes of all 5 drones $\{\mathcal{S}_1, \dots, \mathcal{S}_5\}$, and calculate the union of shielding time intervals for M_1, M_2, M_3 respectively.

For the j -th missile, extract all shielding intervals targeting it $\{[t_{start}^{(1)}, t_{end}^{(1)}], [t_{start}^{(2)}, t_{end}^{(2)}], \dots\}$, and calculate the total length of their union:

1. Sort by start time
2. Merge overlapping intervals (if $t_{start}^{(i+1)} < t_{end}^{(i)}$, merge into $[t_{start}^{(i)}, \max(t_{end}^{(i)}, t_{end}^{(i+1)})]$)
3. Sum the lengths of all merged intervals

Finally, return the total shielding time:

$$J(X_{fly}) = \sum_{j=1}^3 T_{cover,j} \quad (92)$$

The advantage of this method lies in decoupling the complex temporal coordination problem: the outer layer is responsible for "positioning" (planning the flight path), and the inner layer is responsible for "output" (finding the best firing time), greatly reducing computational complexity while ensuring solution quality.

6.5.6 Solution Results

Using the two-layer optimization algorithm and solving with MATLAB, the optimal strategy for the coordination of 5 drones and 3 bombs to intercept 3 missiles is shown in Table 8 below. It can be seen that the 5 drones deployed a total of **9 smoke grenades** (not reaching the maximum of 15), with a total effective shielding time of 26.6 seconds, as shown in Figure 12. Analyzing this result, we can see that M_1 and M_2 received most of

Table 8: Detailed Plan for Five-Drone Coordination

| Drone | Smoke Grenade | Deploy Time (s) | Detonate Time (s) | Target | Shield Duration. (s) | Effective Interval (s) |
|---|---------------|-----------------|-------------------|--------|----------------------|------------------------|
| FY1: 88.19 m/s, 178.35°(3.11 rad) | | | | | | |
| FY1 | #1 | 0.00 | 3.00 | M1 | 3.80 | [3.0–6.8] |
| FY1 | #2 | 1.00 | 4.00 | M1 | 3.80 | [4.6–8.4] |
| FY2: 110.93 m/s, 283.65°(4.95 rad) | | | | | | |
| FY2 | #1 | 6.00 | 9.00 | M2 | 4.00 | [9.0–13.0] |
| FY2 | #2 | 8.00 | 13.00 | M1 | 0.80 | [24.8–25.6] |
| FY3: 108.05 m/s, 121.72°(2.12 rad) | | | | | | |
| FY3 | #1 | 28.00 | 35.00 | M2 | 3.40 | [37.8–41.2] |
| FY3 | #2 | 25.00 | 32.00 | M3 | 3.00 | [35.6–38.6] |
| FY3 | #3 | 26.00 | 33.00 | M1 | 1.60 | [49.4–51.0] |
| FY4: 135.80 m/s, 262.62°(4.58 rad) | | | | | | |
| FY4 | #1 | 1.00 | 12.00 | M2 | 4.40 | [15.0–19.4] |
| FY5: 134.90 m/s, 123.38°(2.15 rad) | | | | | | |
| FY5 | #1 | 13.00 | 18.00 | M1 | 4.00 | [19.6–23.6] |

the resources ($5 + 3$), while M_3 only received 1. This **uneven distribution** is a rational choice made by the optimization algorithm based on the goal of maximizing total shielding time—concentrating limited resources on the "most cost-effective" targets rather than pursuing an average distribution. Analyzing the shielding timeline for M_1 , we find: [3.0, 8.4] s: Two smoke grenades from FY1 provide continuous shielding (with a 0.6s overlap, totaling 5.4s). [19.6, 23.6] and [24.8, 25.6] s: FY5(#1) and FY2(#2) provide relay shielding. [49.4, 51.0] s: FY3(#3) supplements shielding in the missile's terminal phase (1.6s). It can be seen that M_1 experiences a three-phase shielding pattern: early, mid, and late stages, but there is a significant gap in between (8.4 ~ 19.6 s, lasting 11.2s). At the same

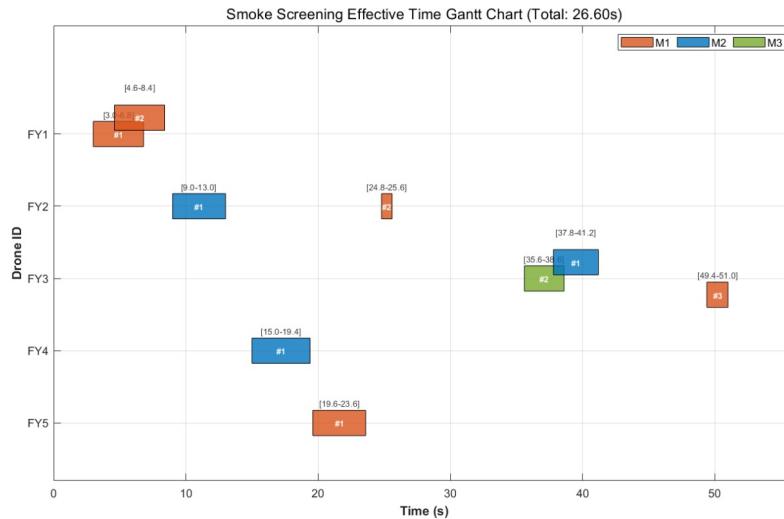

Figure 12: Optimal Strategy for Five-Drone Coordination

Table 9: Problem 5 Target Allocation and Shielding Time Statistics

| Missile | Number of Smoke Grenades | Source Drones | Total Shielding Time (s) |
|---------------|--------------------------|--|--------------------------|
| M_1 | 5 | FY1(#1,#2), FY2(#2), FY3(#3), FY5(#1) | 11.8 |
| M_2 | 3 | FY2(#1), FY3(#1), FY4(#1) | 11.8 |
| M_3 | 1 | FY3(#2) | 3.0 |
| Total: | | | 26.6 s |

time, analyzing the 60% utilization rate of smoke grenades from the 5 drones, we can infer that not all deployments yield positive returns. In certain spatial positions and time windows, even deploying smoke grenades cannot effectively shield any missiles (for example, when the smoke grenades have descended to the ground before the missile arrives). The greedy algorithm did not find enough high-quality solutions (shielding duration $> 0.5\text{s}$) in the candidate set, so some drones terminated deployment early. If each drone is forced to deploy all 3 smoke grenades, the total shielding time may actually decrease (low-quality smoke grenades occupy time windows, affecting the coordination of other drones).

7 Model evaluation

The model established in this paper is based on the physical background and operational constraints of the problem, and reasonably simplifies the motion processes of missiles, unmanned aerial vehicles (UAVs), and smoke screen decoy projectiles. For the highly coupled multi-UAV, multi-smoke screen projectile, and multi-time decision-making problems in the problem, this paper proposes a two-layer optimization framework of an outer genetic algorithm and an inner greedy strategy. The outer genetic algorithm is responsible for the global search of the flight speed and heading of the UAVs, avoiding the problem that traditional local search methods are prone to fall into local optima; The inner greedy strategy, under the condition of a given flight trajectory, efficiently schedules the timing of smoke screen projectile deployment, and quickly obtains an approximately optimal bomb-throwing plan through candidate set generation and constraint screening.

7.1 Advantages of the model

- Considered the physical settling characteristics of smoke grenades, consistent with actual battlefield environments.
- The algorithm has strong generality and can be extended to larger numbers of drone swarms.
- Adopted a hierarchical optimization structure to reduce the computational complexity of high-dimensional combinatorial optimization problems.
- Simplified the true target to key line-of-sight points, avoiding unnecessary three-dimensional geometric calculations, making shielding determination highly efficient while maintaining accuracy.

7.2 Disadvantages of the model

Although the model in this paper performs well in terms of computational efficiency and strategy effectiveness, it still has certain limitations. For example, the model does not consider the impact of wind fields on UAVs and smoke cloud diffusion, and assumes that the missile flight path remains straight without interference, which may have deviations in complex battlefield environments.

7.3 Directions for model improvement

- The current model assumes that missiles are non-maneuvering; future work could incorporate terminal maneuvering countermeasures.
- The model does not consider the impact of wind fields on object motion; wind field models could be introduced to model motion.
- Future work could integrate reinforcement learning methods to further enhance the model's adaptability and intelligence.
